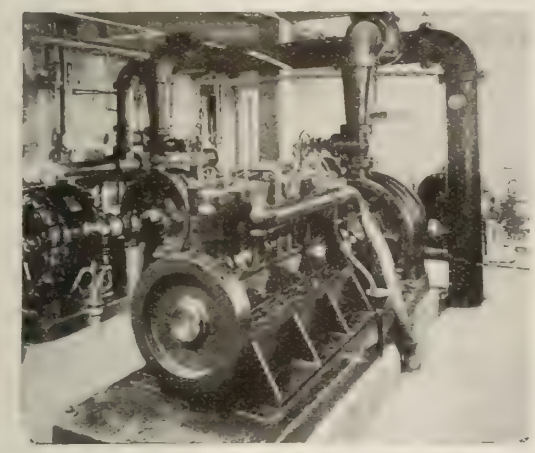
THE ENGINE of REFINEMENT
For the finest boats that float

HIGH SPEED EMERGENCY POWER PLANTS

12 to 300 H. P., 400 to 1400 R. P. M.
For centrifugal pumps and electric generator drives.

UNUSUAL EFFICIENCY



Sterling 85 H.P. engine direct connected to Worthington 3-stage fire pump at Cartierville, Quebec. Capacity 1,250,000 Imperial gallons in 24 hours. This engine has been in operation over 4 years, and has never given trouble in any way. It has a record run of 7 days and 7 nights, 24 hours per day continuous running at top speed and full load without stopping.

PROMPT DELIVERIES

Sherbrooke, Que.

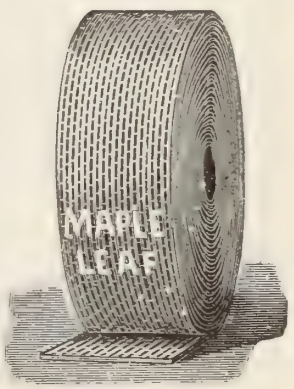
Montreal Office:
404 New Birks Building

Dominion Belting Company, Limited
Hamilton, Canada

Sole Manufacturers of the celebrated "MAPLE LEAF" Brand Stitched Cotton Duck Belting and Belt Dressing.

The demand for our products has steadily increased because the standard of quality has been maintained.

We make only one grade, the best that can be produced.



"MAPLE LEAF" is the strongest, truest running, most economical and efficient belt on the market for transmission of power, conveying, etc.

Being thoroughly waterproof it is suitable for running in wet or dry places. **"MAPLE LEAF"** Belt Dressing is different to others offered in that it is equally good for all kinds of belting, leather, rubber or Balata, as well as our own make.

Write us for prices, and if desired we will be pleased to furnish samples and further information.

A trial order will convince you of their utility.

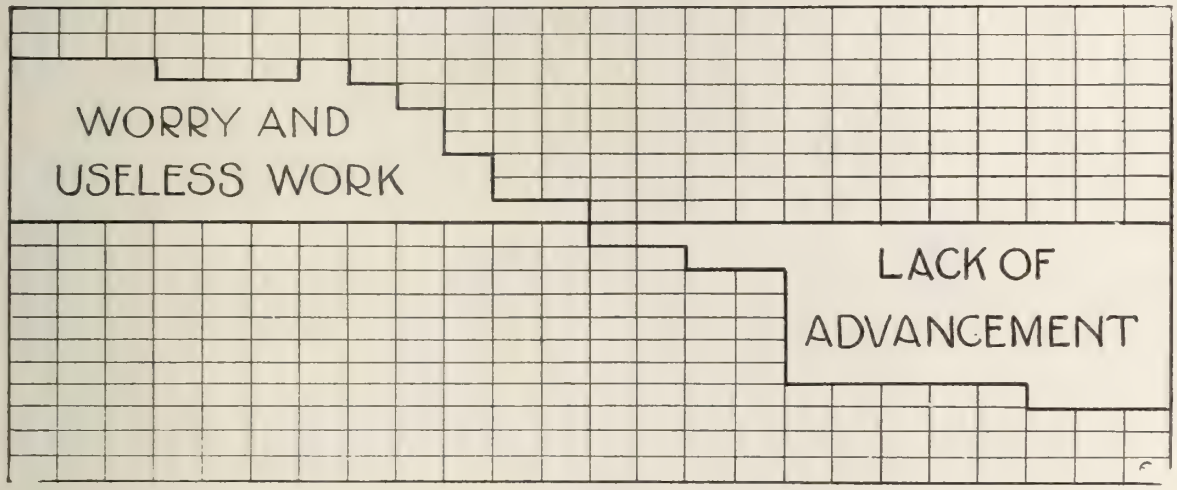
Let the C.A.S.E. Smooth Out Your Load Curve



Remove The Peaks of Worry And Unproductive Labor And Build Up The Valleys By Working For Your Advancement

A man who is thoroughly grounded in the practice of his profession, who is free from personal worry and trouble, overcomes the many difficulties besetting the path of the operating engineer with little labor and in a manner ensuring his advancement.

The successful man owes his success to a wise appreciation of the advantages and mutual help offered by association with those in the same field of endeavor. To join an association having for its objectives the welfare of the engineer in things mental and material, his advancement in knowledge and skill, his protection by provision for sickness and distress is to take advantage of an opportunity indispensable to all who hope to better themselves.

If you are interested in such an organization and live where less than fifteen engineers are located, send for a copy of our constitution and application blanks for admission to nearest branch lodge. If there are more than fifteen engineers in your community, get together and send for particulars regarding formation of a branch lodge.

J. H. HALE, General Secretary,

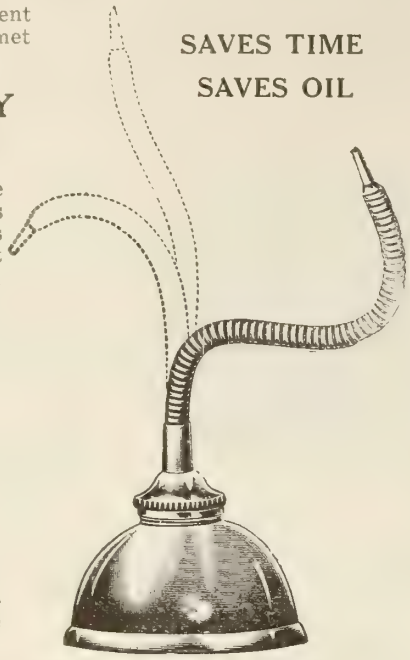
Bend the Spout
to suit position

Every requirement satisfactorily met with

ALL-WAY OILERS

SAVES TIME
SAVES OIL



Note the flexible spout. It enables you to oil all places — many places that previously could only be reached with force pump cans with specially bent spouts.

Indispensable to those who know. Will last as long as six ordinary oil cans. Saves 50% of oil bills.

Ask your dealer to show you the complete ALL-WAY line of oilers. If he cannot do so, please write to us.

Put a Farnsworth System to Work in Your Steam Plant

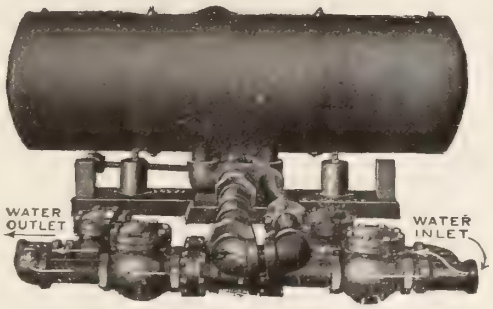
Farnsworth-equipped plants produce more steam with less fuel and less expense than other plants. Thousands of dollars are being saved by the Farnsworth System, not alone in Canada and United States, but in all countries of the world, wherever steam is used for heating or manufacturing process work—its value is thoroughly proven!

When the amount of expense saved by Farnsworth equipment is taken into consideration the question of installation costs is eliminated. It quickly pays for itself. It is a safe and profitable investment. Experience proves that in the majority of cases only three to six months' operation is required to return first costs.

These are facts. Plant owners have nothing to lose and everything to gain by investigating the Farnsworth System and the engineering staff of The Canadian Farnsworth Co. will be glad to advise and co-operate with them in solving steam line drainage and boiler feeding.

The Farnsworth Automatic Duplex Boiler Feeder

The "Farnsworth" should not be confused with ordinary steam traps. It is a machine built for Boiler Feeding. Note the cushioned dashpots, a feature which provides against shocks and ensures smooth operation.



The Sign of Coal Saving

No leaky steam valves with the Farnsworth in your plant; no constant waste of steam to the outside air; no springs to loose their tension; no levers to jump out of place; no weights to cause poundings, and no triunions to bind and stick, or leak water and steam.

The Duplex feature of construction ensures a continuous flow of feed water to the boiler. Then, the machine being always equalized with the boiler provides against sudden shock or jar in the feed lines. There is no hold-up on the return lines as is the case with ordinary return traps, as the feeder is constantly receiving the water.

Our expert steam and condensation engineers are at your service. Have them investigate and make reports.

MARK

Type "K"

Jenkins Bros

Brass Gate Valves

Jenkins Type "K" Brass Gate Valves are designed on novel and graceful lines and are the most popular line of gate valves in use in the power houses of Canada today. The simplicity of the closing mechanism, ease of operation and reliability are some of the reasons why engineers prefer them.

The bodies of Jenkins Type "K" Brass Gates Valves are globe-shaped, which, with the even distribution of the metal, insures great rigidity and strength—preventing distortion due to strain and shock. All parts are carefully machined to gauge and the metal is of the highest quality.

There's a Jenkins Valve for every purpose.

Jenkins Bros. LIMITED

The Diamond Trade Mark is cast on every genuine Jenkins Valve — demand it. Stocks at all dealers.

McEWEN HIGH-SPEED AUTOMATIC ENGINES

These dependable engines are built for continuous duty. They are your best insurance against costly repair bills and unexpected shut-downs.

They operate quietly and smoothly with an exceedingly close regulation under fluctuating loads. Sturdiness and their large reserve capacity enable them to respond instantly to heavy peak load demands.

Your careful investigation of their actual service performance record in all parts of the country specially requested. Let us send you our list of McEwen users.

Built in simple and compound units up to 700 H.P. capacity. May we send you descriptive literature?

Giant Semi-Diesel Oil Engines are built in capacities from 12 to 200 H.P., both single and duplex types; also for operation on gas. Engine units for general power purposes, or complete electric generating or pumping plants, can be supplied to meet any service conditions.

Highest efficiency *automatically*

THE fullest advantages of fuel oil as a source of economical, dependable power are obtained through complete combustion, properly timed and regulated, in accordance with load conditions. The simple ignition and regulation system in Giant Semi-Diesel Oil Engines injects oil into the cylinder late in the stroke. The fly-ball type governor automatically releases the exact amount of oil for the amount of power required. The hot-tube ignition system quickly gasifies and ignites it. Complete combustion is the result. And *fuel input* is kept constantly proportionate to *power output* independent of human attendance. Giant Oil Engines are ideal prime movers for most power purposes. Ask for Bulletin.

New Truths and Old Fallacies

Fusibility of Alloys

Of the many correlative sides of equal importance to a babbitt metal discussion, it is difficult to fix upon any choice in the order of precedence, but we shall first discuss the fusibility of Alloys.

When the tin supply became scarce, because of the war, the Bureau of Investigation and Research of the War Industries Board, of the United States Government, made inquiries as to the best babbitt formulas containing reduced percentages of tin which could be used as substitutes for Genuine Babbitt, and they specifically asked our opinion concerning a mixture containing 50 per cent. tin.

In response we expressed the opinion that only two babbitt compositions were seriously worth considering—one a strictly tin base (Genuine) babbitt; the other a strictly lead base babbitt containing a comparatively small quantity of tin.

We gave as our reason for this seemingly revolutionary advice the extreme low fusibility of all intermediate grades of babbitts, whatever their composition, which makes them highly susceptible to the influence of frictional or initial heat and limits their usefulness to the nature of conditions under which they are used.

We recommended that tin could best be conserved by confining the use of Genuine Babbitt to thin shell bearings, which, by reason of the loose play and pounding made malleability of prime importance. For all other bearings where the lining was secured by recesses or soldered, or well seated, we recommended a well balanced, properly made lead base metal, maintaining that it would wear longer, run cooler and give the most economical service.

Continued next month.

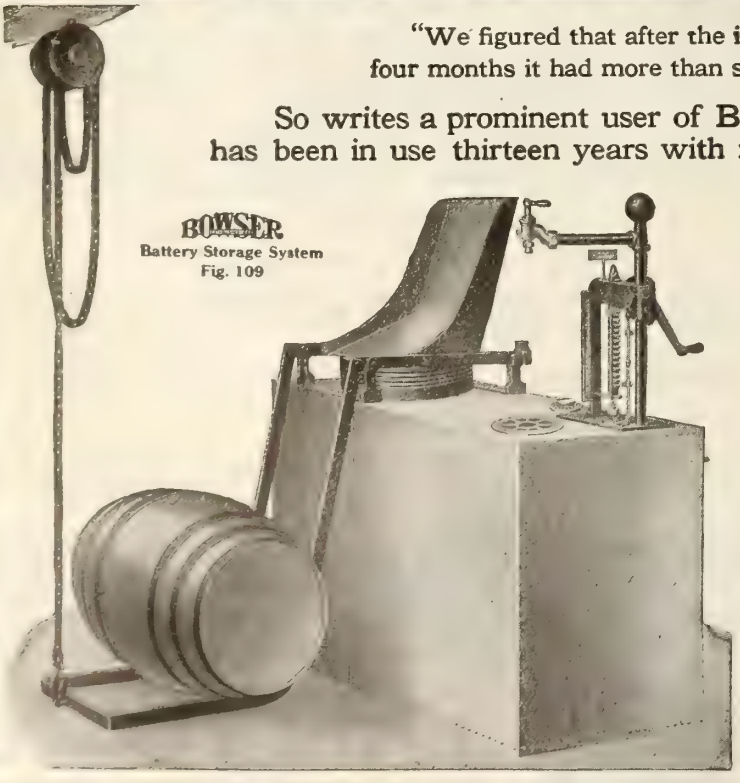
Why Don't You Save Too!

"We figured that after the installation had been in three or four months it had more than saved its entire cost."

So writes a prominent user of Bowser Oil Storage. Their equipment has been in use thirteen years with no operating troubles or upkeep cost.



If you are not using Bowser Storage Systems for your oils you are losing money every day.

"SAFEGUARD"
AUTOMATIC WATER GAGE

POSITIVE PROTECTION

¶ When a "Safeguard" gage glass is broken, your boiler room attendants will not be exposed to the dangers of shutting off the gage valves in the midst of escaping steam and scalding water. The quick, positive action of the "Safeguard" will automatically protect them and also prevent the burning of your boiler plates, as might happen when a boiler is nearly drained through a broken gage glass.

PERFECT OPERATION

¶ The automobile ball-valves of the "Safeguard" close only when glass is broken and positively drop away from their seats as soon as the new glass is inserted. This feature makes the gage operate perfectly at all times and wholly prevents the showing of a false water level and the dangers which might result. We feel confident that the "Safeguard" is the utmost in automatic water gage construction.

Keeping the World's Largest Boilers Operating at High Efficiency

When engineers design boilers of 2,350 H.P. and over, they find it necessary to construct enormous, many-galleried boiler rooms, equipped with elaborate coal and ash-handling systems, and fitted with many delicate measuring instruments. The initial cost of such plants may run into hundreds of thousands of dollars.

To justify this investment — to protect it — to earn dividends upon it — it is absolutely essential that the boilers continuously produce more steam per pound of coal than would normally be obtained with the operation of smaller units. High operating efficiencies being not merely desirable, but **imperative** if the plant is not to prove a white elephant, how are they to be obtained?

Through Clean Heating Surfaces!

Nearly, if not fully, **90** per cent. of the world's boilers of 2,350 H.P. and over, are equipped with Diamond Soot Blowers.

(Names of plants and details upon request.)

This fact is of tremendous importance to every boiler operator. If Diamond Soot Blowers are essential to the economical operation of the world's largest boilers because of their ability to save fuel and labor, and to increase boiler efficiency, they are just as necessary on smaller boilers, and just as desirable from an investment standpoint.

Diamonds usually pay for themselves twice over in a year. You owe it to your plant to obtain full information. Ask for Bulletin 280.

LET RILEY STOKERS REDUCE YOUR COSTS

Riley Stokers are always on the job—you can rely on them to be at work every day. They are tireless—working all hours of the day and night without complaint.

Industrial plants can cut their operating costs to a minimum by using Riley Underfeed Stokers. Consider the following facts:

EFFICIENCY—Boiler tests on Riley Stokers have shown over-all efficiencies of 80% and higher.

LABOR SAVING—One or two men can replace ten or twelve required for hand firing. Continuous, automatic discharge of ashes means elimination of drudgery in fire cleaning. Labor for ash handling in a well laid out plant is negligible.

COMPLETE COMBUSTION—The underfeed method and moving grates intimately mix the proper amount of air and coal, giving perfect combustion.

THE STOWE STOKER

Its fundamental principle is a conveyor feed, positive in action from coal-hopper to ash-pit.

In addition, the Stowe Stoker abounds in many new applications of other well-recognized principles. One such application is (see illustration across page):

The scientific distribution of the air supply

The *conveying elements* (A) alternate with rows of short, stationary *tuyeres* (B). These tuyeres are interchangeable and are made in several widely-varying percentages of air-space.

Forced-draft is employed.

Each stage of combustion is provided with the proper tuyere for its particular air requirements.

The fuel-retarding mechanism (C) brings about a heavy fuel-bed at the ash-discharge end of the stoker. This thicker fuel-bed, together with tuyeres of minimum air-opening, reduces the air supply where the fuel is nearly spent; but the intensity of draft is just as effective here as at the forward end, where two to three times as much air is provided to take care of the destructive distillation of bituminous coals.

These interchangeable tuyeres, plus the high draft pressure *throughout* assures *correct air distribution* —one vital requisite for high fuel economy.

We also manufacture the L-C Chain Grate Stoker—the Dominant Natural-Draft Type for Higher Volatile Coals

Looking Ahead

ONE reason why so many owners of refrigerating plants insist on insulating their cold rooms with Nonpareil Corkboard is because of its established reputation for durability. These men know that under average conditions Nonpareil Corkboard will last practically as long as the building itself.

The main reason for the remarkable durability of Nonpareil Corkboard is the ability of its sole ingredient—clean, ground cork—to resist moisture. Cork, being cellular in structure, possesses no capillary attraction. Therefore, it does not take up moisture from the atmosphere and in a short time become watersoaked, moldy and unfit for use.

The results of insulating refrigerated rooms with Nonpareil Corkboard are low operating costs, long service and practical freedom from repairs.

Sharp freezer in the plant of the Hazelwood Dairy Company, Spokane, Wash. Insulated with Nonpareil Corkboard.

After you have read the interesting book, "Nonpareil Corkboard Insulation," you will realize more clearly why it is that Nonpareil Corkboard is the preference of so many owners of refrigerating plants who appreciate real merit. Send for a copy today.

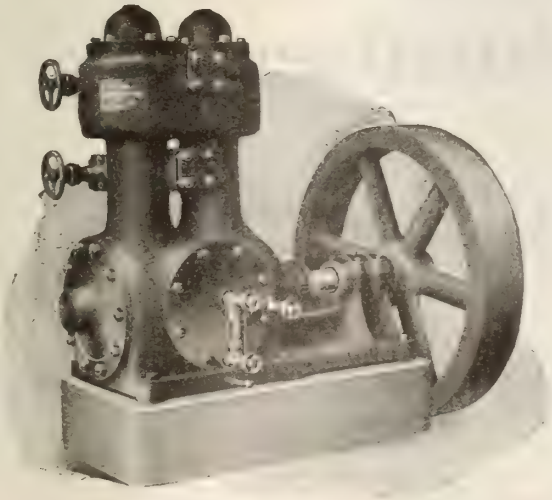
Mechanical Refrigeration



Reliable--Beneficial

THE many benefits common to all users of MECHANICAL REFRIGERATION should make it a valuable adjunct to **your** business.

The uniform temperatures it provides have a better holding effect on the product in storage than ice, because the temperature produced by ice is not uniform, varying with the amount of ice in the refrigerator.

MECHANICAL REFRIGERATION permits the maintenance at all times of any temperature desired in the refrigerators or cold storage rooms, whereas you can not always get ice just when you need it, and a delay of even a few hours often means a loss through deterioration of the product in storage.

If interested in MECHANICAL REFRIGERATION, a request for information and prices will receive our prompt attention.

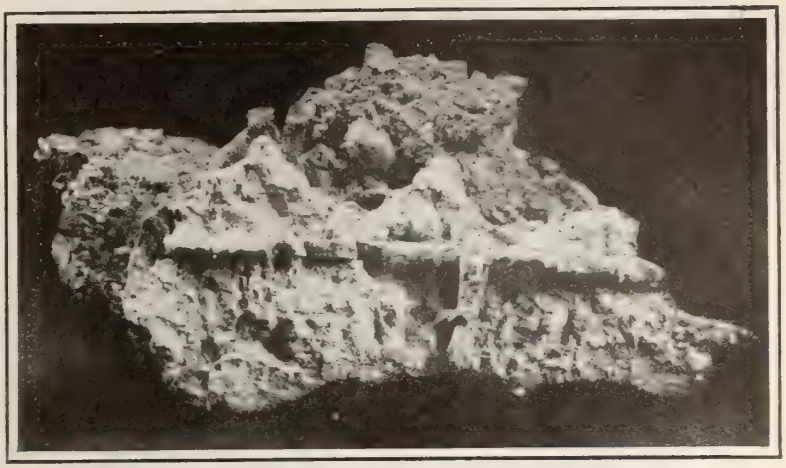
Why do clinkers stick to fire-box walls?



An example of slice-bar clinker surgery, which would have been unnecessary if the brick had been protected.

THIS picture of a piece of clinker which in being sliced away has taken with it part of the faces of two bricks and the mortar between the bricks is a typical example of the way clinkers destroy fire-boxes.

You know clinkers penetrate the surface of unprotected fire brick and cling to them, and if there is not a perfect joint, the clinkers eat in there as well.

The way to prevent clinkers from penetrating into fire-box walls is to use Johns-Manville Heat Treatment.

The joints of Johns-Manville No. 26 and 31 High Temperature Cement are extremely elastic and of high tensile strength — they do not fall out from between the bricks. This prevents spalling, which is so common when ordinary, easily loosened fire-clay is used — yet allows for expansion and contraction.

A further treatment, consisting of a coating of No. 32 High Temperature Cement on the surface of all brickwork exposed to the fire, gives protection that makes a fire-box nearly invulnerable to heat and clinkers.

Ask for the booklet on Johns-Manville Heat Treatment and learn how to prevent what may be happening to your fire-box walls.

Continuous service and low maintenance cost due to the self-cleansing seat

LUNKENHEIMER "DURO"

BLOW-OFF VALVES

Remain tight under the most severe operating conditions because the self-cleansing seat feature eliminates the cause of most of the wear to which Blow-off Valves are subjected.

This self-cleansing seat feature,—exclusive in Lunkenhiemer "Duro" Blow-off Valves, functions automatically when the valves close by cutting off the inlet and allowing only a fine spray of water to pass, thereby removing foreign substances which may have lodged on the seat during the blow-off period.

In addition to the self-cleansing seat feature, the disc is reversible and has seat faces made of a durable alloy which readily accomodates itself to any irregularity in the seatring insuring tight though easily operated valves.

To further enhance their durability as a whole, all the parts are renewable.

Lunkenheimer "Duro" Blow-off Valves have proved their merit in service and are specified where boiler mountings of the better grade are desired.

All standard sizes, in material combinations to suit a wide range of pressure and temperature conditions.

Your local dealer can furnish them; if not, write us.

Power Plant Features of the *Quaker Oats Mills* at Peterborough, Ont.

By W. F. Sutherland

THE Quaker of by-gone days, with his, to our eyes, curious dress and his well-known simplicity of life, would seem to have little in common with present day industry; yet he is one of the characters made most familiar to all of us through present day advertising. When the word "Quaker" comes before our eyes in the course of our reading, we naturally and instinctively associate him with a particular cereal, so dear to the heart of the Scotchman. It is not surprising then, that an extensive industry has grown up around this trade character and it is only to be expected that the power plant would be an important feature in the milling of the rolled oats, wheat flour and other products manufactured by the Quaker Oats Company. This is the case and the present article is devoted to a description of the power plant equipment which supplies energy to their mill at Peterborough, Ont.

While water powers such as Niagara Falls and others of comparative size are spectacular in their picturesqueness and valuable for the amount of power they are capable of developing, many smaller ones exist throughout this country, and these, while of limited size, are of much value in the industrial development of their immediate neighborhood. The River Otonabee flows through Peterborough, and a surprising amount of power is there developed both by the Hydro-Electric Power Commission and by the Quaker Oats Company, which owns its own power plant, and operates it by means of a subsidiary organization known as the Hydraulic Power Company.

Originally built in 1902, the plant now consists of the usual dam and tail race, generating station, a short transmission line and a substation at the mill of the Quaker Oats Company.

River Characteristics

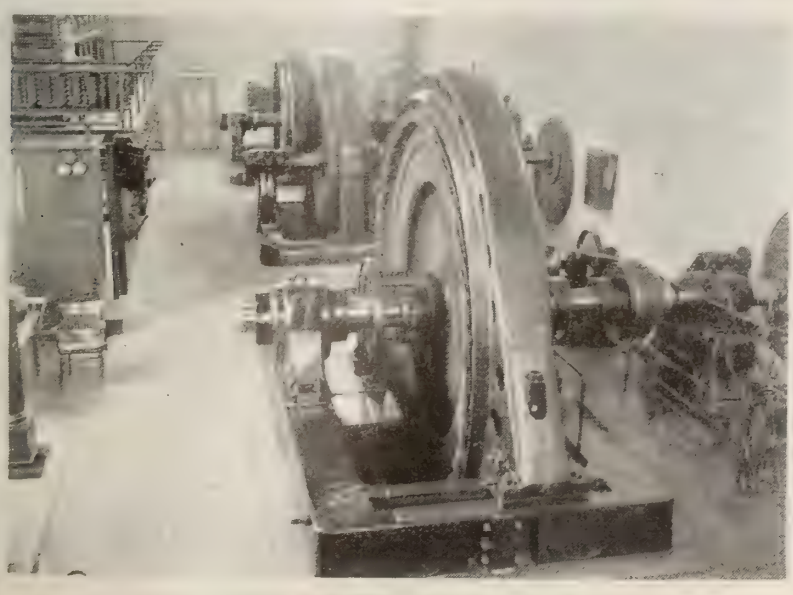
A pondage of about 7,000,000 square feet is created by the dam and a normal head of twenty-eight feet results. The flow is sufficient under the worst summer conditions to generate under the above head 3,000 kw. on 24-hour service. Incidentally the plant is operated continuously 24 hours per day and 365 days a year.

Anchor ice is usually prevalent between the first of December and the end of March but its effects on plant operation are never very serious. It usually settles on the racks and can usually be removed. In the last five years only one shut down has occurred from this source. This is true insofar as the main generating units are concerned, but considerable trouble has been experienced with anchor ice trouble in the exciter wheels, these being smaller and more liable to trouble from this source.

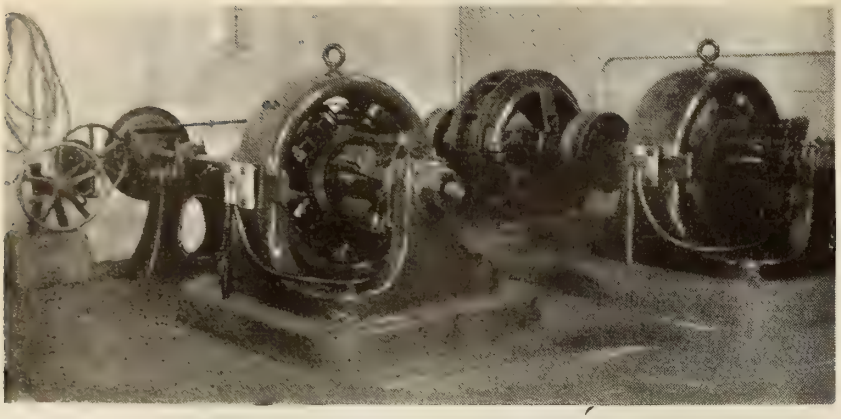
The fore-bay is well designed to eliminate float ice which is carried over the dam and down the river. It is estimated that about 50 per cent. of the winter stream flow is run off for this purpose.

Generators and Wheels

Three direct connected units are installed in the power house with a total



VIEW IN POWER HOUSE SHOWING GENERATORS.



EXCITER SETS IN POWER HOUSE.

capacity of 4,375 K.V.-A. Three-phase power is generated at sixty cycles and 2,300 volts. The first unit, installed in 1902, is rated at 1,500 kv-a and is direct connected to a Samson turbine, made by the Wm. Hamilton Manufacturing Company, Peterborough. The generator is of Canadian Westinghouse make and the unit is controlled by Lombard oil pressure governor. The speed is 150 revolutions per minute.

Unit No. 2 is a Canadian General Electric generator rated at 1,875 kv-a and driven at 180 revs. per minute by a Leffel runner, made by James Leffel and Company, Springfield, Ohio. This runner is in a Wm. Hamilton casing. This unit was installed in 1919 and is the most modern of the three.

Governing is accomplished by a 12.5 in. by 14.7 in. Woodward governor, made by theWoodward Governor Company, Rockford, Ill. It is extremely sensitive, and controls the speed to within very close limits. The oil pressure carried in 200 lbs. per square inch, and means for adjustment is provided so that the amount of gate opening can be controlled at various loads. Safety devices are also fitted and remote control is installed so that the unit can be shut down from the switchboard.

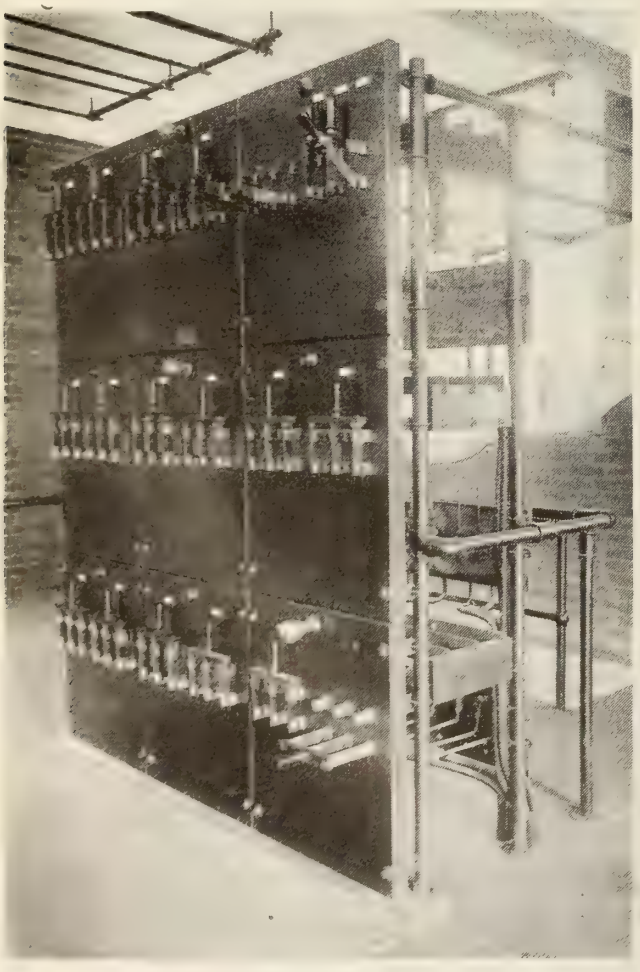
The third generator, installed in 1908, is also of Canadian General Electric manufacture, and is rated at 1,000 kv-a. It is driven at 180 revs. per minute, by a Leffel type wheel and is controlled by a Lombard governor similar to the first one installed.

Exciters

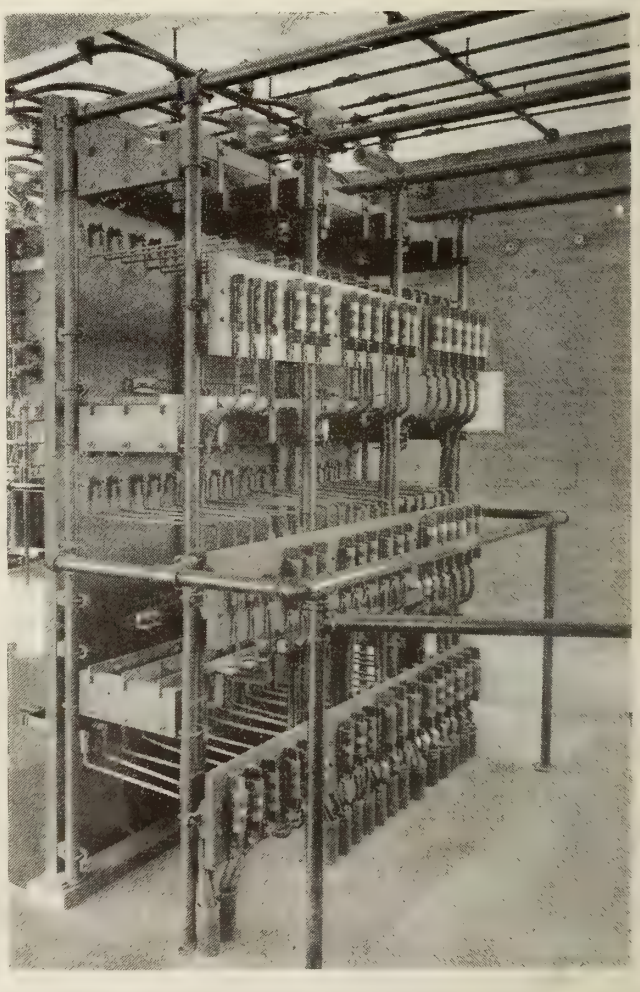
Two exciter units are provided, driven by individual wheels. The first is 75 kw. capacity, and generates current at 125 volts. The speed of the wheel and generator is 454 revs. per minute. The second unit is of similar construction and size, except for the fact that the generator has been moved forward and an induction motor, direct connected between the wheel and the generator. This induction motor is of 100 h. p. capacity and takes energy from the station busbars at 2,200 volts. Anchor ice trouble is overcome by its aid, for so soon as the exciter slows down the motor picks up the load and carries on till free running conditions are restored again.

Operating Characteristics

Mention has been made of the fact that anchor ice causes little trouble. Little has b en experienced from other causes and since the capacity of the plant is more than ample, one generator is usually held in reserve, each generator being cut out in turn. Every fall the wheels are thoroughly overhauled as well as the generators and the latter are painted.



FRONT VIEW OF LIGHTING BOARD IN SUBSTATION.



REAR VIEW OF LIGHTING BOARD, SHOWING BUSSES

Switchboard

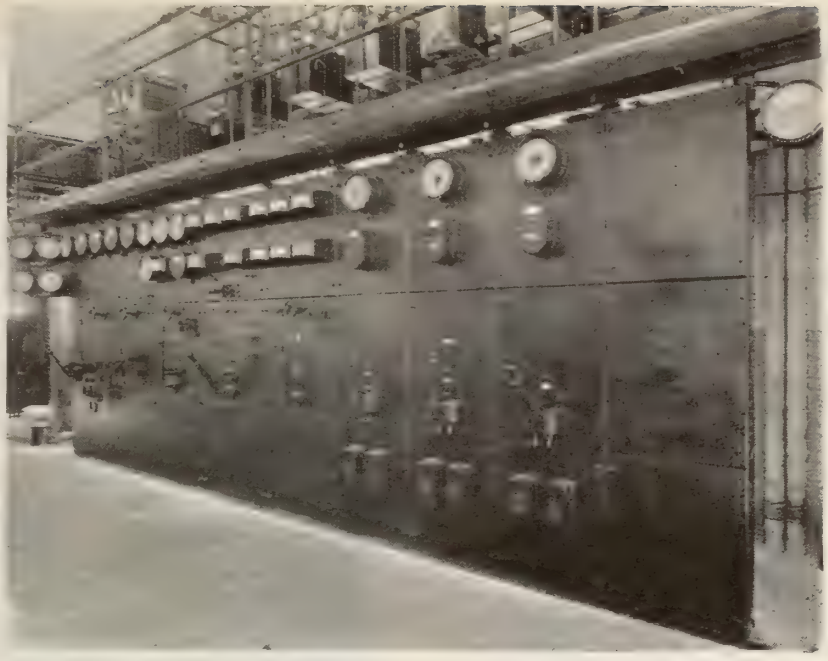
The switchboard in its present shape was installed by the Northern Electric Company, and carries the main generator control panels together with exciter panels, etc. The 2,200 volt bus-bars, and oil switches are mounted above on a gallery, and control is effected by mechanical remote control from the switchboard below.

The swinging bracket on the left of the board carries two voltmeters, a synchronoscope and a frequency meter. The panel controls the induction motor on the exciter set. It carries an ammeter, Canadian Westinghouse overload series trip relays and Condit oil switch control. A synchronizing plug and an ammeter jack for testing ammeter and relays, completes the equipment.

The next two panels are exciter panels, and both are provided with ammeter, voltmeter of Westinghouse make; field rheostat control, and a three-pole 250-volt, 1,000-amp. switch.

The fourth panel controls the 1,500 kv-a generator, and is fitted with the usual equipment, ammeters, indicating polyphase wattmeter, power factor meter, d. c. field ammeter, field switch and rheostat, and a governor control switch. A Condit oil switch of 800 amp. capacity controls the output of this generator.

The net panel controls the 1,875 K.V.-A. machine, and its equipment is in some respects different from that mounted on the one just described. Only one ammeter is mounted instead of the three on the Westinghouse panel. A temperature indicator is mounted on this panel which indicates in degrees centigrade the temperature at four different places in the coils of the generator. Temperature coils are inserted in field coils at the top, bottom and each side, and the operator controls the output solely from the indication thus furnished. A power factor indicator an indicating wattmeter, and a d. c. ammeter complete the metering equipment. The field rheostat is of the remote controlled type. An 800 ampere Condit oil switch, hand operated, remote controlled, is installed and the governor control button is also mounted.



FRONT VIEW OF MAIN SWITCHBOARD IN POWER HOUSE.

The third generator panel is exactly similar to the last one described, but without the temperature indicator.

Feeders

Three feeds run from the power house to the mill substation, and provision has been made for a fourth. The first of these is of 300 amp. capacity, and takes care of the lighting load. The switchboard panel is equipped with a Sangamo integrating wattmeter, a control handle for the Condit 300 amp. oil switch and two overload series trip relays.

The other two feeders are equipped in a similar manner, except that 800 amp. switches are installed and the wiring is increased in size to correspond.

The usual current and potential transformers, together with disconnecting switches, for isolating parts of the circuit upon which work is being done, are all installed in the switch structure above. Two static ground detectors are installed.

The feeders are carried down from the switch structure to the floor and underneath it to the wall, where they rise to the lightning arrester gallery immediately under the roof. Here they pass out and overhead to the substation. The lightning arresters are of the electrolytic aluminum cell type.

From the power plant a short pole-line carries the 2,300 volt feeders to the substation located adjacent to the mills and to one side of them.

GENERAL VIEW OF SUBSTATION SHOWING ARRANGEMENT OF TRANSFORMERS LOW TENSION DELTAS AND LEADS.

Substation Layout

The present substation is a thoroughly modern structure and represents the latest in construction and layout. It is a two-storey structure of brick and reinforced concrete. The first floor is laid out to accommodate the power transformers. This floor is provided with a mezzanine or gallery which provides access to low tension bus-bars, junction boxes, etc., and also carries a portion of the lighting transformer equipment. The second floor is laid out as a switchroom and here all the switchboards, high-tension, power, and lighting are located; the lightning arresters for the incoming high tension lines are also located on this floor.

On this level, access is had to the main mill buildings by a bridge, crossing over the tracks below. This bridge also serves to carry all the power and lighting feeder conduits to the mill.

High Tension

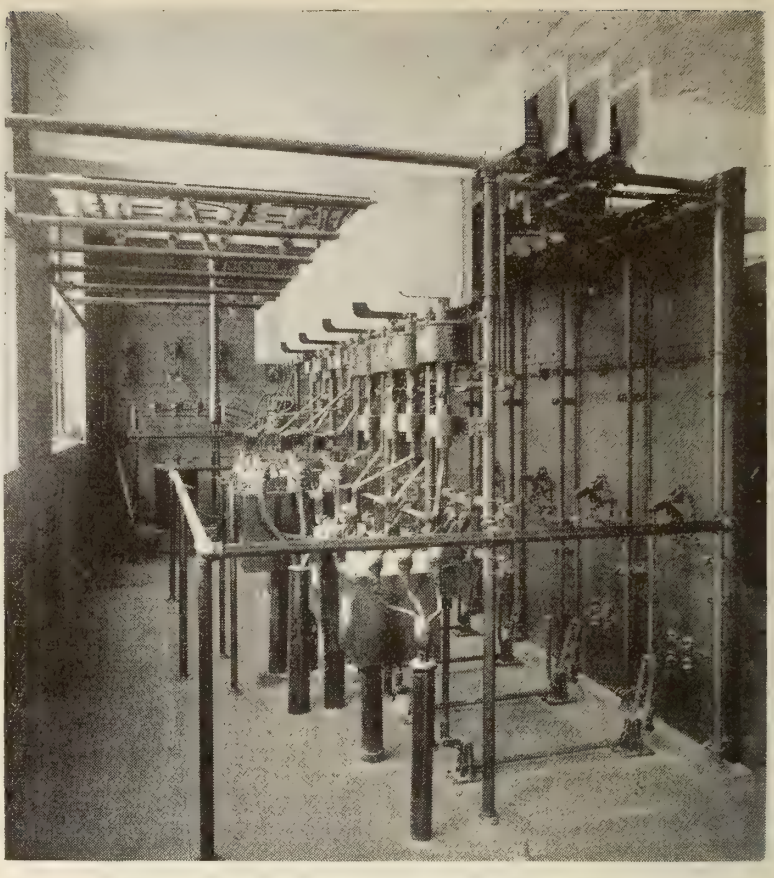
The high tension feeders for power and lighting enter below the roof

through wall bushings. Canadian General Electric lightning arresters, of the electrolytic type are provided, and the usual choke coils and disconnecting switches are installed. The two power feeders are each 500 M.C.M. cable while the lighting feeder is No. O.

2,300-Volt Switchboard

The 2,300 volt switchboard contains six panels as will be seen from the accompanying illustration. The first panel from the left controls a 2,300 volt feeder direct to the soft wheat mill and the one next to it, a similar feeder to the hard wheat mill. The equipment for both these feeders is the same, 300 amp. Condit oil switches, Westinghouse single pole circuit opening relays, Weston ammeter and Sangamo wattmeters. It will be noticed that only one ammeter is mounted on each panel although the circuits are three-phase. Only one is necessary since the feeders operate induction motors and all phases are balanced. The next two panels are equipped with the necessary oil switches, relays and ammeters for controlling the high tension side of the two banks of transformers. The switches are 800 amp. Condit oil switches equipped with the usual trip coils and in addition overload releases. These latter are not used for the opening of the breakers under overload conditions but form part of a safety trip circuit possessing some novel features.

Each bank of transformers is fed from the bus-bars through disconnecting switches and the oil switch. The secondary side is not provided with oil switch nor circuit breaker but in their stead knife switches are installed on the low tension board. It would be thus possible for an operator to attempt to open these under load with disastrous results. To obviate this, auxiliary contacts are provided on the knife switches and when the switch is opened a fraction of an inch these complete the circuit through the overload coils on the oil circuit breakers, thus tripping them. It is then impossible for the attendant to open the knife switches under load since the transformer will be cut out and the only current flowing will be magnetizing current from the low tension bus-bars. When the oil switch is opened the auxiliary trip circuit is automatically broken by an additional set of contacts located on the oil switch mechanism.



REAR VIEW OF 2200 VOLT SWITCHBOARD IN SUBSTATION

The next panel is spare and the last one controls the high tension side of the lighting transformers. It is provided with a Condit 300 amp. oil switch, reverse current relay and Weston ammeter. In this case some unbalance of load may be expected and for this reason an ammeter jack is provided by which readings may be taken on any phase.

The lighting feeder is the only one equipped with an oil switch the two power feeders being tied in solidly on the bus, disconnecting switches only being provided.

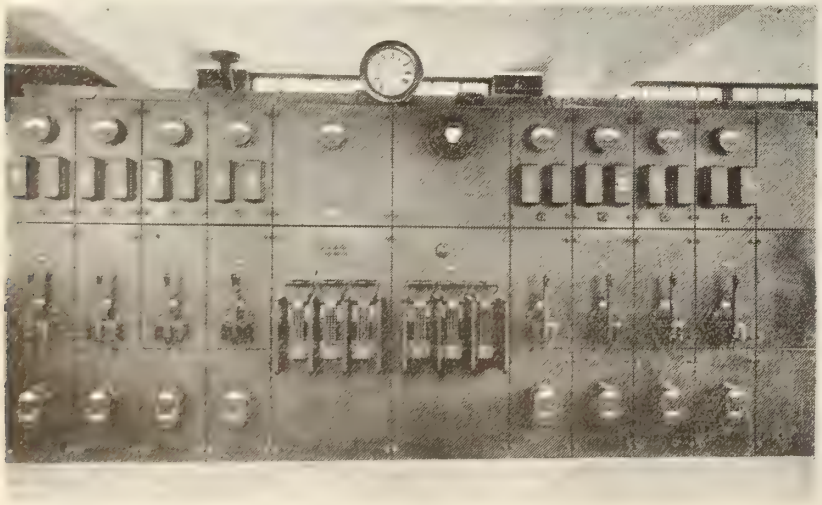
The oil switches are all pipe mounted at the rear of the board and it will be noticed that attention has been paid to the safe guarding of all live parts. The bus-bars and individual phases of the disconnecting switches are all separated by barriers. The two 2,200 volt mill feeders are equipped with two sets of current transformers, one for relay operation and the other for ammeters.

Power Board

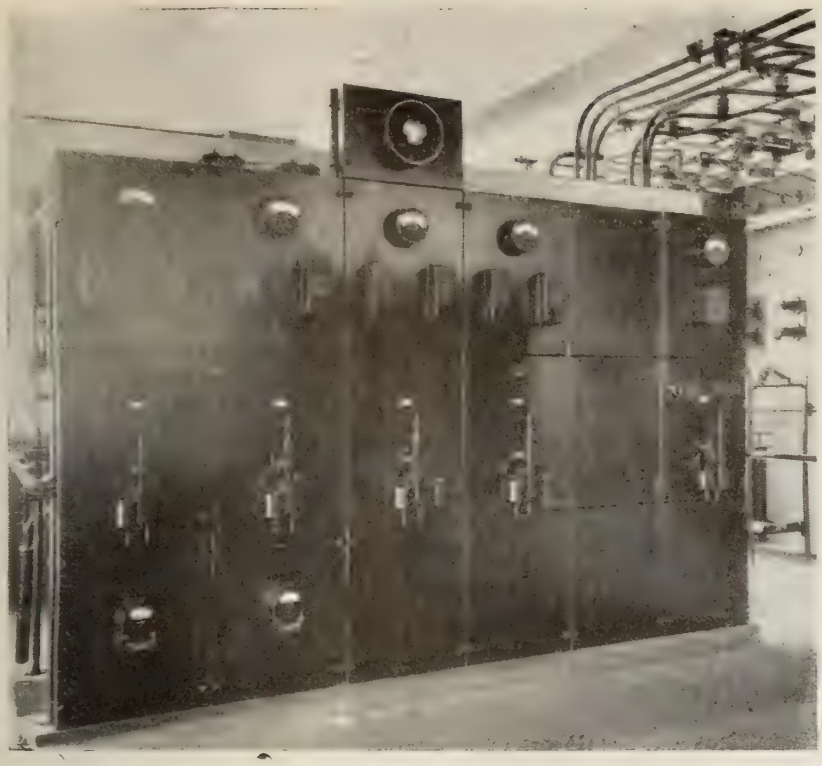
Except for the several large 2,200 volt motors all power for mill drive is supplied at 550 volts. The 550 volt board contains eleven panels, eight of them controlling mill feeders and one spare. The two remaining panels are used for the secondary transformer switches.

The feeder panels are 16 in. wide and mount the Condit oil switches, Westinghouse inverse time limit circuit opening relays, and metering equipment. One Weston ammeter and a Sangamo polyphase wattmeter serve to meter the load. Four of the oil switches are 800 amp. and the remaining four are of 500 amp. capacity.

The two transformer panels carry the transformer switches. These are of the single pole, single throw type and of 3,000 amp. capacity. As mentioned above each switch is fitted with an auxiliary contact which trips the oil switch on the high tension side if through inadvertence, they are opened under load. One of the



REAR VIEW OF 550 VOLT SWITCHBOARD IN SUBSTATION.



FRONT VIEW OF 2200 VOLT SWITCHBOARD IN SUBSTATION.

transformer panels carries a Weston volt meter and volt meter plugs while the other carries a ground detector.

The rear of this board, shown in one of the accompanying illustration, is of interest. The oil switches are mounted on pipe framework free of the slate panels and are operated by the usual pipe mechanism. Each circuit is provided with disconnecting switches placed between the current transformers and the bus-bars. Two sets of transformers are mounted on each feeder, one for the relays and the other for the metering equipment. The low tension leads from the transformers to the knife switches and from them to the bus-bars are encased in asbestos wood for protection. All live parts are securely taped or otherwise insulated where accidental contact is apt to occur.

The 800 ampere feeders are of 800 M.C.M. capacity two 400 M.C.M. leads being run in parallel for each phase. The 500 ampere feeder is of 500 M.C.M. capacity. All leads are taken in conduit through the floor to a junction box at the end of the run to the mill.

Lighting Switchboard

Mention has been made of the fact that a 2,300 volt feeder is run direct from the power plant to the substation for lighting purposes. This feeder passes through a 2,300 volt oil switch on the high tension board and then goes to the lighting transformers below. These are six in number and are of 40 kw. capacity each. The secondaries are brought out three wire 110/220 volt, each separate phase being carried to a separate bus on the lighting board.

This lighting board consists of three 24 in. panels mounting in all 18 three pole knife switches. The first panel from the left controls the transformer secondaries and mounts six switches. The remaining switches control the lighting feeders to the various departments of the mill.

One noticeable feature of this board is the absence of fuses in front. All circuits are fused and by reference to the accompanying illustration it will be seen that these are arranged in a very neat manner at the rear. Each circuit is taken off the bus-bars by means of flat copper to the upper terminal of the knife-switches and from these to the fuse-blocks by means of round copper. From the fuse-blocks the circuits are taken to the floor level where conduit is provided. The three sets of bus bars are noticeable in the illustration.

It may be mentioned in passing that all the switchboards were installed complete by the Northern Electric Company of Montreal and Toronto.

Transformer Equipment

Two banks of power transformers are installed. Each consists of three 666 kv-a single phase, oil insulated, self-cooled Canadian General Electric transformers. Each bank is connected up delta-delta. The transformers are placed on raised platforms and are mounted on wheels running on tracks which engage with tracks of a like gauge on a portable truck running lengthwise of the building. It is thus an easy matter to remove any transformer in case of failure. All transformers are provided with a two-inch connection to an oil tank. Provision is thus made for draining and filtering the oil when such is required.

The illustration in which the transformers are seen, shows the arrangement of the low tension leads and deltas to advantage. The low tension copper is suspended from the gallery and ceiling by means of a pipe framework.

A feature of the motor drive in the mill is the direct connection of two of the larger slow-speed motors to the line shafts they serve. This feature, together with other motor drives, will be described in a later article, together with some of the more interesting belt drives installed by Sadler & Haworth, Toronto.

The Possibilities of Pulverized Fuel—II

Concluding Portion of an Article on Pulverized Fuel Abstracted From the Report on Pulverized Fuel Issued by the Commission of Conservation

By WILLIAM J. DICK, M. Sc.

Puget Sound Traction, Light and Power Company

In describing the results secured from the operation of a test plant for the Puget Sound Traction, Light and Power Co., Mr. Henry Hull says:

Prompted by the large amount of unmarketable fine coal, which is piled up at numerous nearby coal mines, the Puget Sound Traction, Light and Power Company has investigated the practicability of burning pulverized coal. This coal is a form of lignite particularly adapted to use in the pulverized form, owing to the high volatile constituent and the very high fusing point of the ash. To prepare this coal for burning it must first be thoroughly dried and the moisture content reduced to approximately 1 per cent. before it can be properly pulverized. It must then be ground until approximately 85 per cent. will pass through a 200-mesh screen and 95 per cent. through a 100-mesh screen if the best results are to be obtained. It should then be fed directly to the furnace, or, if transportation or storage is necessary, it should be kept air-tight so far as possible to prevent absorption of moisture.

The coal which has been investigated by the Puget Sound Company is dried and pulverized by the Pacific Coast Coal Company at its briquetting plant, near Renton, which is equipped with a Raymond pulverizing plant. It is then loaded in a box car having a metal-lined hopper. The car is spotted at the steam plant over a chute which is connected to the car by a flexible hose. The chute feeds a small metal-housed conveyor, which elevates and dumps the coal into a bunker adjoining the power plant. From the bottom of this the fuel is fed, by means of two motor-driven screws, into a 3-inch (7.62-cm.) supply pipe, through which it is then blown to the front of the furnace. At this point the fuel is discharged into the side of an injector, consisting of a 16-inch (38.1-cm.) drum, surrounding a nozzle on the end of a 10-inch (25.4-cm.) air-supply pipe. Dampers are provided in the drum and air pipe to regulate the amount of air supplied to the combustion chamber. In starting operation the coal dust is allowed to drop on an oil flame, although any small fire built under the fuel discharge pipe would have the same effect. An extended Dutch oven, with a broad arch, is used to assist ignition, as considerable combustion space is required to secure satisfactory results, a parabolic shape being most desirable. Fire cannot travel back into the fuel supply pipe as long as the rate of air supply is greater than that of fuel propagation.

A record of a 12.8-hour test on the equipment is given herewith. The duration of the test was limited by the facilities for storage and handling of the fuel. The coal was weighed in the car as delivered to the plant and the net weight determined by a subsequent weighing of the car after unloading. The test was run until all coal was consumed. The water was measured by a Venturi water meter installed in an individual feed line to the boiler, and all instruments were checked for accuracy before starting.

During the test it was noted that the boiler could be forced to 200 per cent. of rating without any apparent damage to brick setting or tubes. The stack was perfectly clear under these conditions, and there was no fusing of the ash. About one-third of the ash was found deposited in the second and third passes of the boiler, none whatever being found to have collected on the tubes.

Test of 300-Horsepower B. and W. Boiler Burning Pulverized Coal

(Coal analysis)

Moisture	5.4
Volatile	37.2
Fixed carbon	37.

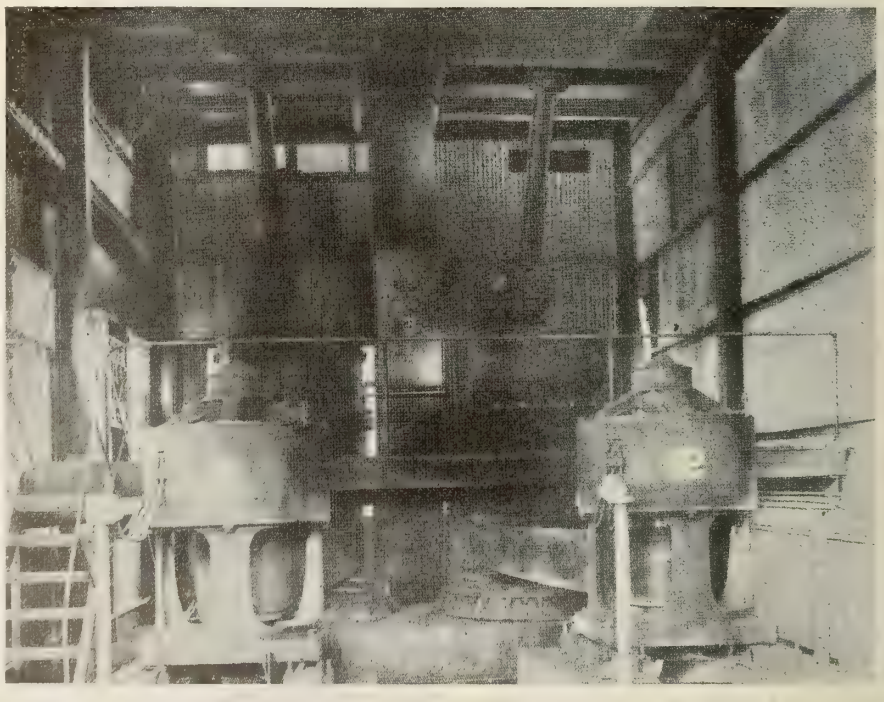
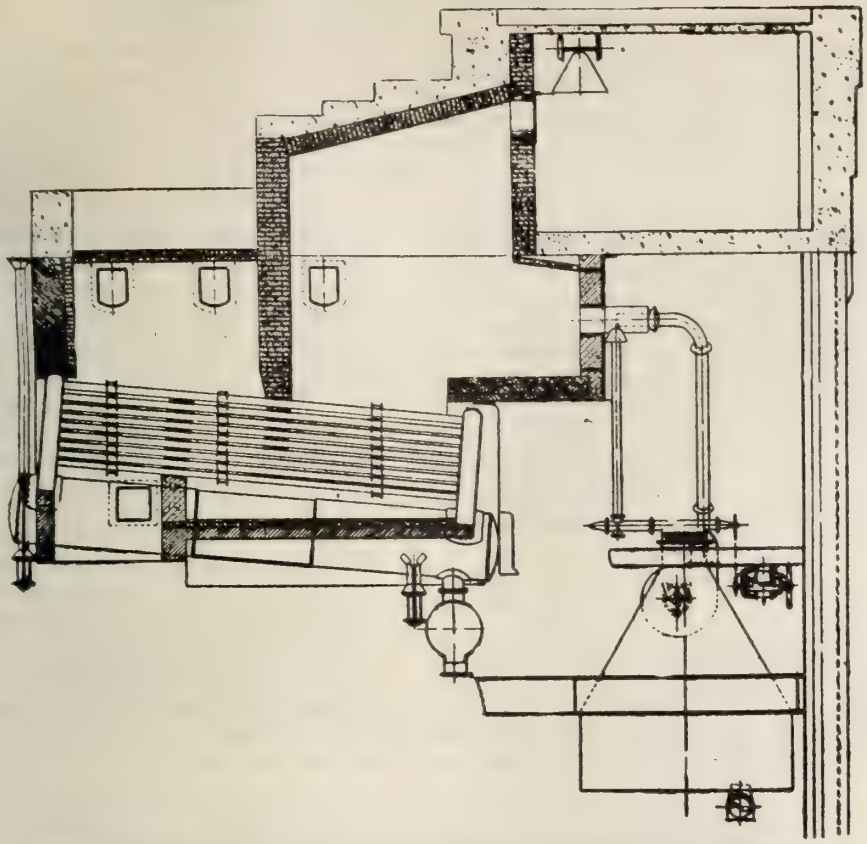
The result of the experiment tends to refute most of the adverse criticism of this method of burning coal. There was no formation of slag in the furnace or on the tubes, there was no shower of cinders and ashes emitted from the smokestack, and



FULLER LEHEIGH PULVERIZER MILLS FOR PULVERIZING LOW GRADE COAL FOR BURNING UNDER BOILERS. MISSOURI KANSAS AND TOPEKA RY., PARSONS, KAN.



CROSS-SECTION OF 250-H.P. O'BRIEN BOILER AT PARSONS, KAN., SHOWING GENERAL ARRANGEMENT.

there was no damage done the boiler from heavy overload under these conditions.

From the experiments in burning these various fuels it was found that—assuming pea coal at $1.60 per gross ton ($1.76 per net ton)—the prices which could be paid for other fuels on the basis of equal heating values are as follows: Pea coal on chain grates, $1.60 per gross ton, delivered; fuel oil 56 cents per barrel, delivered, and pulverized coal, $2.20 per gross ton, delivered.

The temporary plant was designed by E. B. Powell, of the Stone and Webster Engineering Corporation. of Boston, Mass.

The Puget Sound Traction, Light and Power Company have recently installed a pulverized fuel plant and have converted all their boilers for the use of this class of fuel.

Metallurgical Industries

The application of pulverized fuel has been developed to a very considerable extent in connection with various kinds of metallurgical work.

In the iron and steel industry some 2,000,000 tons is used annually in various types of furnaces, such as open hearth, heating, puddling, soaking pits, continuous heating, reheating, annealing, forging furnaces, and furnaces of practically every description where heat is required.

It is very evident that the future possibilities of the application of pulverized coal are now being recognized by the large steel companies as a subject worthy of their careful investigation. The Manitoba Bridge Company is installing a pulverized coal plant in connection with its open hearth steel furnace at Selkirk, Man. The Armstrong-Whitworth Company, of Longueuil, Que., has installed a plant for its heating furnaces.

A great development has taken place in the application of this class of fuel in connection with the copper industry—ore-roasting furnaces, reverberatory and copper-melting furnaces of all types. Between 1,000,000 and 2,000,000 tons of pulverized coal is used in this industry alone each year.

International Nickel Co., Copper Cliff, Ontario

When the reverberatory plant of the International Nickel Co., at Copper Cliff, Ont. was built in 1911, the furnaces were designed to be fired with pulverized coal, and the necessary machinery for preparing the coal was installed.

The original furnaces were put in commission in December, 1911, and almost from the first the new method of firing proved a success. There was some trouble from ash accumulating at the throat, but, when the furnaces had been brought up to a good smelting rate, this ceased to cause any serious inconvenience. Some ash always tends to deposit at this point, and it should be removed each day. It is in a semi-molten state when deposited, and tends to build up rapidly if not removed at regular intervals. Pulverized coal has been used in this plant ever since, and there has been no reason to doubt the wisdom of adopting it. In the last few years the use of pulverized coal in reverberatory work has almost entirely supplanted grate-firing, and in a number of instances has even replaced oil-firing.

Pulverized Coal for Power Purposes

Replying to a request for information, Mr. Blythe D. Rogers, President of the British Columbia Sugar Refining Co., Ltd., of Vancouver, B.C., gave the following data:

"We require sufficient fuel to maintain 2,500 boiler horse-power at about 175 per cent. rating, or something over 4,000 actual horse-power. The coal used is an unwashed slack coal, containing about 33 per cent. ash, and having a calorific value of about 9,300 B.t.u. For the specified horse-power, we require to pulverize about 125 tons of coal per day, spread over a period of twenty-four hours. For this purpose we have installed a dryer, heated by means of pulverized coal, and three Fuller mills, each capable of pulverizing from five to seven tons per hour. Additional equipment consists of a magnetic pulley for separating iron particles, nails, bolts, etc. from the coal, a crusher for breaking up large lumps and the necessary bins, conveyors, etc. The whole plant requires a separate building about 120 by 40 feet, and 40 feet high.

"In the boiler room the coal is fed by screw-feed mechanism to the furnace, where it is caught up by a current of air and blown into the furnace. Little alteration had to be made to the return-tubular boilers on account of their large combustion chamber, but in both sets of water-tube boilers (Badenhausen and Babcock & Wilcox) Dutch ovens had to be built, as pulverized coal requires a very much larger furnace than oil producing equal horse-power.

"As far as we have gone with the experiments to date, the installation has proved very satisfactory from an economical standpoint. At 160 per cent. of rating the combined boiler and furnace efficiency is 76 per cent. under test condition.

"The drawbacks not yet overcome consist mostly of trouble with ash, which is natural in a coal of such high ash percentage. Tubes in return-tubular boilers plug solid with ash in a very short time. Beside this, large quantities of dust are thrown out into the atmosphere from the stacks, which constitutes a very serious difficulty; this we are grappling with at present. I believe that, with this problem satisfactorily solved the installation of pulverized coal will be shown to be an unqualified success."

Pulverized Fuel Installation, Parsons, Kansas

In 1916, the Missouri, Kansas and Texas railway installed a plant at Parsons, Kansas, for preparing and burning pulverized low-grade coals, including lignite, under boilers, This installation is stated to be the largest commercial installation of its kind in existence.

The boiler plant consists of eight O'Brien 250-h.p. boilers arranged in one continuous row of three-and-one batteries, respectively, there being a space between the settings of each pair of two boilers of 4 ft. 8 inches, and a space between the two batteries of 28 ft. 4 inches for feed pumps, auxiliaries, etc. At one end space is allowed for four more boilers. The boilers carry 150 pounds per sq. in. steam pressure; the temperature of feed water is 208 deg. Fahr. Based on a boiler efficiency of 70 per cent., operating full capacity for 10 hours, and half capacity for 14 hours, about 79 tons of coal would be consumed in 24 hours by ten boilers. When the installation is complete a total of 94 tons, per day of 24 hours, will be required. The principal advantage derived from the use of pulverized coal at this plant is that inferior grades of coal can be burned successfully, also, its use in the boiler-room reduces the number of attendants to a minimum. This reduction in labor costs

partially offsets the cost of pulverizing the coal.

Pulverizing Plant

The coal is dumped directly from the cars into a concrete-and-steel hopper beneath the track. As a large percentage of the coal is run-of-mine the coal from the hopper is crushed by a 20 x 24-in. spike-toothed roll crusher. From the crusher the coal is elevated by a 20-in. belt conveyor through an inclined tunnel and discharged into the coal plant. At the discharge end of the conveyor the coal is passed through a magnetic separator and discharged into a pair of 28 x 18-in. corrugated rolls. From the rolls the crushed coal is elevated, discharged into a screw conveyor and carried to a 40-ton bin situated at the back end of the dryer. From the bottom of the bin the coal is fed by screw-conveyor to the back end of a 4 1-2 x 30—foot indirect-fired rotary dryer. From the dryer the coal is elevated and discharged into a 45-ton bin situated over the pulverizers. The pulverizing plant consists of two 75-ton pulverizing mills, furnished by the Fuller Company. From the mills the pulverized coal is elevated and conveyed by screw-conveyor to bins in the boiler house. One bin is situated in front of each pair of boilers. The bins have a capacity of 10 tons each and, therefore, provide for a run of 20 hours at full capacity. The bins are rectangular, but have divided hopper-bottoms, thus enabling the coal to be fed by separate feeders to each boiler. Each feeder is chain-and sprocket driven by a 2-h.p. variable speed motor, the control of which is situated in a convenient position in front of the boilers. The coal is discharged from each feeder, through a 3-inch pipe, into a funnel-shaped opening in the top of the burner nozzle. The burner consists of an outside cylindrical pipe, 14 inches in diameter, one end of which projects into the furnace; a 7-inch blast pipe is inserted in the other end for a distance of from 12 to 18 inches. An adjustable metal cover is fitted over the blast pipe so as to regulate the amount of air induced in the burner. The funnel-shaped opening into which the coal is fed is directly over the discharge end of the blast pipe, so that the coal will be drawn in and thoroughly mixed with the blast and induced air before reaching the combustion chamber of the furnace.

The boilers as installed at first had to be changed since, as, on account of the high ash content (22 per cent.) in the coals used, it was found that, with horizontal baffles, there was too much ash accumulation. A Dutch oven, approximately of 6-feet cube, has since been built in front of the boilers; also, vertical baffles were inserted, replacing the former horizontal ones. With these changes highly gratifying results are obtained; no slag is formed, and the ash is readily blown off the floor of the rear chamber with an air hose once a week.

WELDING OF LOCOMOTIVE CYLINDERS

By L. A. North

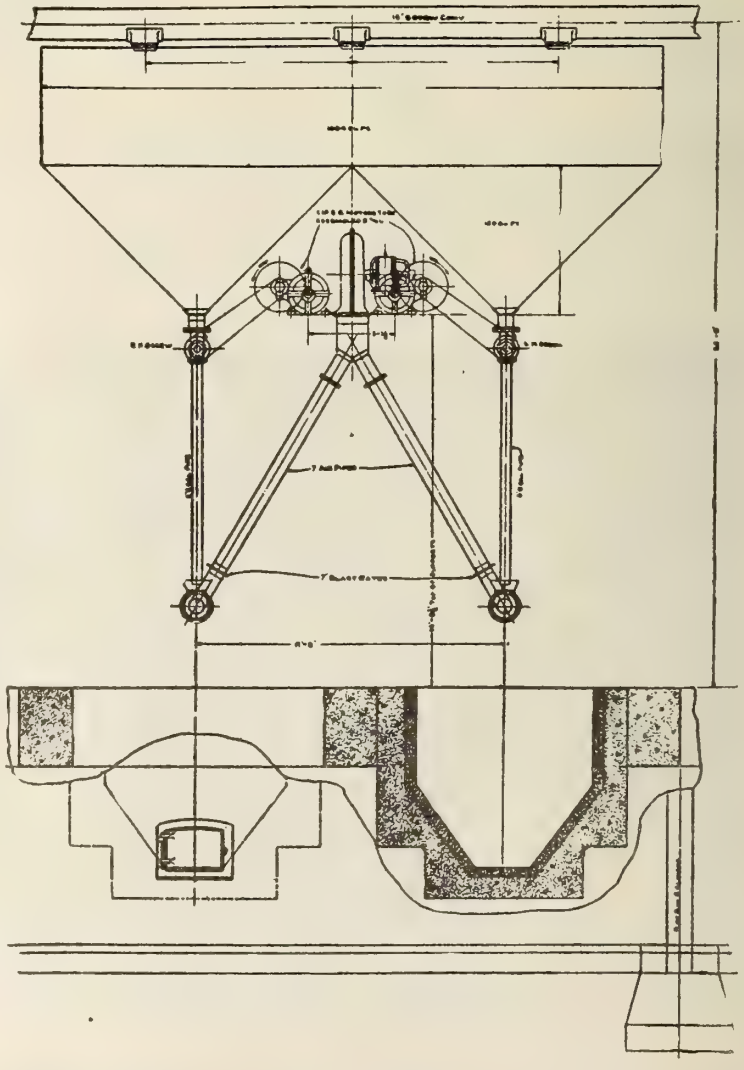
The welding of locomotive cylinders and other parts has been made possible and very successful by the introduction of oxy-acetylene and electric welding. It has been possible to weld locomotive cylinders which formerly would have been scrapped or repaired with either a brass patch or a dovetailed insert of some other metal, the weld in the majority of cases making a substantial and satisfactory job provided the expansion and contraction had been properly taken care of.

Experience has taught us that in order to properly weld a locomotive cylinder or a casting of any make or design, it is necessary to thoroughly pre-heat to insure a uniform temperature in order to properly take care of the contraction and expansion and to avoid cracking after the weld has been made and the metal has been allowed to cool off. The success of any weld of this kind depends largely on the care used in the pre-heating and the judgment of the operator making the weld. We cannot be too particular in the selection of the operator for this class of work.

Some difficult welds have come to my observation, one in particular, where the entire upper portion of the cylinder at the port area had been totally destroyed. This was repaired by having a grey iron patch cast in the foundry, fastened to the cylinder by means of clamps and welded in place. The cylinder was preheated to a uniform temperature to take care of the expansion and contraction. After the weld had been made and the cylinder had cooled down, a reinforcement was added to this weld by drilling through between the stud holes and securing the additional support by tap bolts which were tapped and screwed into the main barrel.

It is possible to weld broken bridges in slide valve cylinders successfully. Recently this was done and effected a saving of two cylinders in place of the one, which was cracked, as the cylinder which was repaired was an obsolete pattern, and had we not been able to make this weld the application of an entire pair of cylinders to this engine would have been necessary. As this engine was one that in a few years will be placed in the scrap pile, I am satisfied that the weld will outwear the present cylinders.

Not having experience with electric welding on cast iron, I am not prepared to enter into a discussion of this method to any great extent, but I have examined a number of castings which have been repaired with the electric welding process, and careful examination failed to disclose any flaw or fault in the weld.—"Welding Engineer."



PULVERIZED FUEL INSTALLATION AT PARSONS, KAN., SHOWING ARRANGEMENT OF PULVERIZED COAL HOPPERS AND FUEL FEED TO BOILERS.

Power Plant Management; Condensers

This Article Takes Up the Various Types of Condensers Seen in the Power Plant and Enters Into the Details of Their Design and Operation

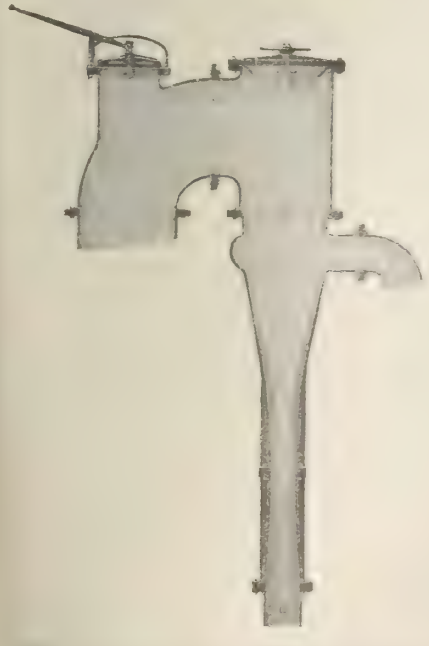
By ROBERT JUNE

THE primary reason for the installation of condensers in power plants is the reduction of back pressure on the prime mover. If saturated steam is confined in a closed vessel and cooled, condensation of the vapor, with a drop in temperature, will result. The greater the drop in temperature the greater will be the amount of steam condensed and the greater the decrease in pressure. In actual practice, all of the steam can never be condensed, since this would call for a temperature of absolute zero—492 degrees below the freezing point; hence, the pressure can never be reduced to zero.

When water is used for cooling, the minimum temperature which can be secured is 32 degrees F., which corresponds to the pressure of 0.0886 lbs. per sq. in., or 0.1804 inches of mercury. This, then, is the lowest condenser pressure which can be obtained.

In a condenser, the processes of condensation and removal of the air and condensed steam are continuous. The tightness of valves and joints, the amount of entrained air, and the temperature to which the condensed steam is reduced, are the factors which determine the degree of vacuum obtained.

There are a number of ways in common use of expressing the degree of



THE BULKLEY INJECTOR CONDENSER.

vacuum. (a) Thus to refer to a 28-inch vacuum is to indicate that the pressure of the atmosphere is 28 inches of mercury higher than the pressure in the condenser. (b) Vacuum may be expressed by percentage; thus to refer to a 90 per cent. vacuum would indicate that with the barometer standing at 30 inches, a vacuum of 27 inches had been secured. With a lower barometer, say 28 inches, it would indicate a vacuum of 25.2 inches. It will thus be seen that expressing vacuum in percentage gives an idea of the efficiency of the condensing steam.

In indicating vacuum, the point of measurement should always be stated, since the greatest vacuum will be found at the air pump intake, the next highest in the body of the condenser, and the lowest at the steam inlet.

Gain in Power Due to Condensing?

As a general proposition, an engine running condensing, will require from 20 to 30 per cent. less steam for a given work than will the same engine running non-condensing. Unfortunately, this decrease in steam consumption is not all pure gain. Steam may be used in creating the vacuum or power necessary to operate the condenser auxiliaries, varying from 1 to 6 per cent. of the main engine power, depending upon the equipment and conditions of operation. The cost of installation and of the maintenance of the condenser must also be charged up against the saving effected. Even if these deductions are made, condensing is found to be a very profitable operation in power plants where the exhaust steam is not used for heating or manufacturing purposes.

Conditions of Condensation

There are many types of condensers in use, but in general, condensing machinery can be divided into two main groups: Surface condenser, where the steam or vapor to be condensed is separated from the condensing water by metal tubes or diaphrams; and jet condensers, where the steam or vapor and the condensing water are brought in actual contact with one another. The jet condenser can further be divided into the regular low jet type, situated generally below the source of exhaust steam or vapor, in which type both the condensed steam and condensing water are discharged to the atmosphere by means of a pump working against a head corresponding to the vacuum in the condensing chamber, which, for a vacuum of 28 inches, corresponds to a head of approximately 31.7 feet, not including friction; and the barometric jet condenser, in which the condensing chamber is placed high enough above the hot well to discharge the condensate and condensing water by over-balancing a barometric column.

A vacuum which will raise mercury against the action of gravity one inch, will raise a column of water 1.132 feet. Therefore, if there were a perfect vacuum in the chamber of the condenser

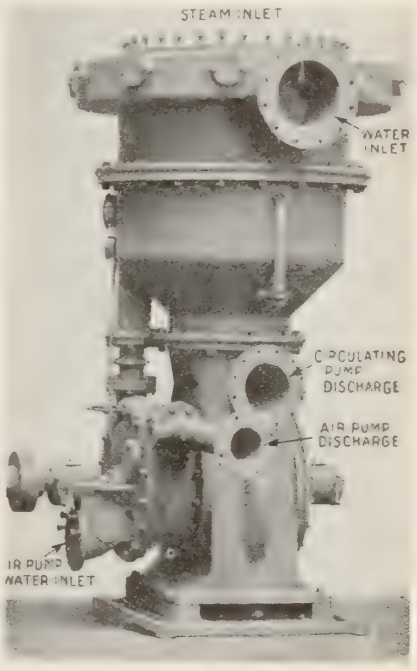


FIG. 2—WESTINGHOUSE LE BLANC CONDENSER.

it would raise a column of mercury 30 inches and a column of water 34 feet, at sea level, against the action of gravity. A vacuum of 28 inches in the chamber would, therefore, support a column of water in the tail pipe 31.6 feet high. If the condensing chamber be placed slightly higher than this from the level of the water in the hot well, any amount of water added to the top of the column will discharge a corresponding amount into the hot well from the bottom of the tail pipe. By this well-known principle of the barometric column, the injection water is discharged from the system, in a barometric condenser, without the use of a pump. The engine or turbine is protected from water being pulled into the exhaust pipe, by placing the upper flange of the condenser higher than 34 feet above the level of the water in the hot well. It is, therefore, unnecessary to rely on any vacuum breakers or check valves to protect the units from damage from this source.

If pure water vapor were delivered to the condenser, it would be a simple matter to create and maintain a perfect vacuum in the air condensing chamber, but, unfortunately, steam always carries with it air and other non-condensible

vapors, which expand in the condensing chamber after the steam has been condensed and which would eventually destroy the vacuum if not removed.

The amount of air in a condensing system varies greatly; but, roughly, the amount of air, measured at atmospheric pressure present in condensing systems on turbines ranging from 500 kw. to 200 kw. may vary from 1 to 15 cubic feet per minute, depending on the condition of the unit.

Air enters a condensing system through three sources; about 4 per cent. of the total amount of air enters through the feed water to the boilers; about 47 per cent. leaks in through stuffing boxes, joints, and porous spots in castings (this amount can be greatly reduced by a little care), and about 49 per cent. of the total amount enters with the condensing water (this figure also can be reduced by having a tight suction line, or by other means described later).

If proper care be displayed in the design, construction, erection and maintenance of the condenser and piping, the air leakage can be greatly reduced, and labor so expended more than pays for itself later. A slight leak in a vacuum line or stuffing box will cause much more waste of coal than a considerable leak in a steam line. Nobody would think of installing an extra boiler to take care of these leaks in the latter case mentioned, although many dry vacuum pumps have been installed to remove air, in the former case, entering the system through leaks. The prevention of practically all leaks in exhaust lines is simply a case of proper design, erection and materials.

To eliminate this air, which is present more or less in all condensing systems, is by far the most difficult problem connected with condenser design and all jet condensers differ from one another only in the means they employ to accomplish this result.

Jet Condensers

We have referred to air elimination as the most difficult problem in condenser design. Let us see how it is met in a few standard makes of condensers:

The Bulkley injector condenser, as the name indicates, removes the non-condensible vapors by the injector action of the condensing water flowing through a contracted throat of special dimensions and designs. The condenser which is illustrated in Fig. 1, consists of an iron casting machined to the required dimensions and fitted with a heavy brass cone.

Water enters the system at B, and circulates in the belt about the brass cone, C, falling through the annular space, G, between the outer circumference of the brass cone, C, and the inner surface of the casting, and forming a moving cone of water, D, with a sharp vortex. Steam enters at A, passing through the interior of the cone C, and meets the water at G, imparting to it what velocity it has on being condensed. This tends to force more water through the annular space. The condensed steam water and non-condensible vapors are brought down through the hollow cone of falling water, D, and the non-condensible vapors discharged through the contracted throat, F.

The lower portion of the condenser expands until it is the same size as the tail pipe, E. This allows the air and non-condensible vapors which have been brought through the contracted throat, F, to expand, thus making it impossible for them to get back into the condensing chamber. They are therefore taken down through the tail pipe and delivered to the hot well.

The Westinghouse LeBlanc jet condenser is illustrated in Fig. 2. Steam entering the top of the condenser meets an incoming charge of water and is quickly condensed; it falls to the base of the condenser and is removed by the centrifugal discharge pump; the non-condensible vapors being ejected through the medium of the LeBlanc air pump. The condenser body, of ample proportions, is made of close grained cast iron, the upper portion of which forms an annular channel for distributing the circulating water through several nozzles

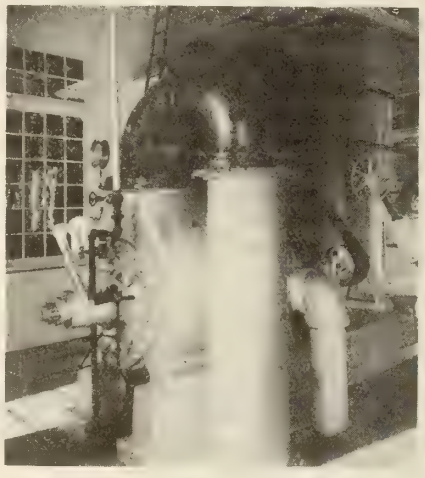

FIG. 3—THE ROTURBO ROTARY JET CONDENSER.

into the condenser. A much faster, and at the same time more intimate mixture of steam and water takes place with the sub-division of this incoming water than if the total quantity of water were passed into the condenser through a single opening. A very powerful breaker is attached to the condenser body and serves to break the vacuum in case of accident to pumps, thus preventing water from rising above the top of the condenser.

The circulating and air pump casings are placed directly beneath the condenser body, and in addition to housing the pump runners, serve the purpose of supporting the condenser. In order that either pump may be removed with convenience and dispatch, without disturbing the other, the casings are cast separately, hand holes also being provided on each pump to facilitate inspection.

In the Roturbo Rotary jet condenser, Fig. 3, the mixture of steam and water is secured by means of a revolving impeller. After the water jets have travelled rapidly some distance, so that the broad parts of the water fans have all combined to form a complete ring of spray and condensed the steam, the problem, as in the case of all other condensers, is to extract the condensate and air with certainty and efficiency, and it is at this point that this condenser differs in principle from all other types.

Instead of giving the water jets, as they leave the injection nozzles in the drum sufficient energy to extract themselves from the vacuum chamber and carry with them, without further assistance, the air and condensate, or instead of letting the condensate accumulate in the bottom of a large condenser chamber, where the air is separated, and from which the air and water are independently extracted by auxiliary apparatus, the rotating jets of spray or condensate with the entrained air are picked up by the blades of an exhaust fan, concentric with the rotating pressure drum, and of a larger diameter, and ejected with certainty and efficiency.

Surface Condensers

Surface condensers consist essentially of a cast iron shell provided with a tube set in each end, into which brass tubes are expanded. The exhaust steam fills the shell and flows around and between the tubes, while the cooling water is forced through the tubes by means of a circulating pump. Contact with the cool tubes condenses the steam and the condensate drops to the bottom of the condenser from which it is exhausted. The Wheeler condenser, which is fairly representative of the best type of surface condenser, is illustrated in Fig. 14. In the Alberger condenser, which is not illustrated, the steam enters through a deep rectangular steam distributing dome, extending nearly the full length of the condenser shell. The sides of this distributing dome slope downward and become tangent to the main shell, leaving an arc of nearly 180 degrees of the tube surface exposed to the entering steam. The construction of this steam dome evenly and effectually distributes the entering steam over the full length and breadth of the tube surface and brings it at once into contact with the greatest possible number of tubes.

With regard to surface condensers, the following points should be given care in choosing such equipment:

1. Upon entering the condenser, the steam should encounter the minimum of resistance practicable, and the pressure drop through the condenser should be just as small as possible.
2. Rapid air removal and freeing from entrained water should be provided.
3. Condensate should be returned to the boiler and freed of air as rapidly as possible, and at as high temperatures as possible.
4. There should be as little obstruction as possible to the flow of the circulating water in all parts of the condenser.

As with other types of equipment, the choice of a condenser for any given plant depends upon the individual conditions.

Engineers differ somewhat in their estimate as to the volume which a condenser should have with reference to that of the engine cylinder with which it is connected, but a generally accepted figure is that the condenser volume should be three-fourths of the engine cylinder.

The general advantages and disadvantages of the different types may be briefly summarized as follows:

Jet Condenser Advantages

1. Least expensive to install.
2. Occupy very small space.
3. Installation does not require hot well pump.
4. Cost of maintenance low.
5. Requires less water than surface condenser.
6. Acidulated or otherwise impure water may be used.

Disadvantages

1. Condensate is wasted.
2. Failure of apparatus might flood turbines.

Surface Condenser's Advantages

1. Condensate can be used for boiler feed.
2. Better vacuum obtainable.
3. Low pumping head.
4. Less chance of losing vacuum because a drop in vacuum does not affect water supply.

Disadvantages

1. High initial cost.
2. Comparatively high cost of maintenance.
3. Large floor area required.
4. Acidulated or impure water cannot be used.

Barometric Condenser's Advantages

1. First cost reasonable.
2. Low cost of maintenance.
3. No danger of flooding turbine.
4. Acidulated or impure water can be used.
5. Requires less circulating water than condenser.
6. No heat well pump required.

Disadvantages

1. Possibilities of air leaks in long exhaust pipes.
2. Loss of vacuum between condenser and turbine amounting to ½ inch or more.
3. Construction not adapted to building plan of many engine rooms.
4. Condensate is wasted.

Where there is a supply of water suitable for cooling purposes and for boiler feed, the jet condenser is most suitable. When the cooling water is not suitable for boiler feed and the separate supply of boiler feed is expensive, the jet condenser is not so desirable, inasmuch as the condensed steam is mixed with the cooling water which is unfit for boiler feed. Under such conditions, the condensate is lost, so that a continual fresh supply of boiler feed must be procured. A surface condenser would be better for this condition since the condensed steam and cooling water are kept separate, and therefore the condensate may be saved and returned to the heater, thus insuring a minimum amount of boiler feed make-up.

Notes on Jet Condensers

With the low level jet condenser, where water enters the condenser by virtue of its own vacuum, the maximum lift should not exceed 18 feet and the minimum not less than 6 feet.

If the cold well cannot be located near the condenser, the greatest care must be exercised to see that all water lines are perfectly air tight.

The amount of water required for the air pump is approximately 15 per cent. of that used for condensing purposes, that amount, as a general rule, being discharged to the hot well.

A head of any more than 10 feet is the maximum against which the air pump is able to discharge, hence, with cooling towers or spray pond installations, the air pump discharge must never be led into the main condenser discharge.

Pipe lines should be as short and as free as possible of air, thereby reducing friction losses to the smallest possible amount. Also use long radius elbows and avoid tees, using flange pipes on all lines subject to vacuum.

The quantity of water used by the air pump should be regulated by a gate valve. A check valve should be provided in the air pump discharge line to provide return flow.

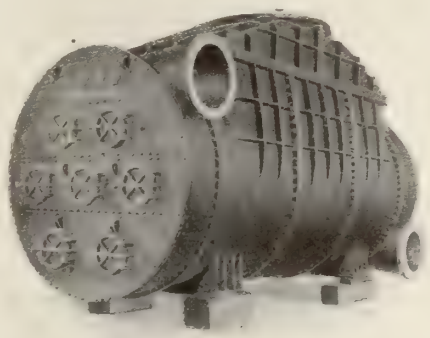

FIG. 4—WHEELER SURFACE CONDENSER.

With turbine driven condensers, a good valve should be provided in the steam line next to the governor valve on the turbine and a drain provided for this valve. An expansion joint should be installed on the exhaust line over the turbine in order to prevent pipe strains which may cause the turbine to get out of alignment with the pumps. With motor driven condensers, the motors must be protected from water. Do not use high voltage; it is dangerous to the operation of hydraulic machines as well as to the operators. Use motors with impregnated windings as a valuable protection against moisture.

The best arrangement for a barometric condenser is one where the level of the cold well is not greater than 18 feet below the centre line of the injection opening on the condenser. With this arrangement the circulating pump is unnecessary.

Avoid long horizontal lines. Make exhaust lines as large a diameter as possible, thus reducing pressure drop to a minimum. Provide exhaust pipes with atmospheric relief valve.

The injection line should be provided with a gate valve for regulating the amount of water used by the condenser. Another gate should be provided in the air line between the air pump and the condenser head.

Notes on Surface Condensers

Study the arrangement of steam paths into the tube bank. The lower tubes are surrounded with films of water and dense air which seriously impede the flow of heat.

See that your condenser tubes are kept clean. With dirty tubes the rate of heat transmission is greatly reduced and the vacuum is insufficient for the efficient operation of the prime mover.

Do not buy a smaller condenser than you need. A uniform high vacuum over operating periods is worth far more than the initial investment saved by reducing the tube surface.

READER'S QUERY

Question.—I have a steam engine with 14 by 18 inch cylinder which requires boring out. This will, of course, make the present piston too small, and I wish to know whether it would be possible to turn it off and shrink wrought iron or steel bands over it. These could be, say, ½ in. thick and could be turned down to fit the cylinder.

Answer.—While it would be possible to fix the piston as suggested, the cheaper course would probably be to have a new piston cast and turned to fit. The machining would be less in amount and the proper dimensions for the rings would be more easily secured. To fit the shrink rings to the present piston would necessitate three machining operations, the turning down of the piston, the boring of the rings and their facing off to dimension after shrinking on the piston.

NEW MONTREAL SALES OFFICE

The Engineering and Machine Works of Canada, Limited, St. Catharines, Ont., owing to increasing business in boilers of all types, tanks, plate work of all descriptions, etc., and particularly in connection with the manufacture in Canada of the Keystone light traction excavator, Model 4, have opened another Eastern sales office in the Birks Bldg., Montreal. This is in addition to their sales office in the Sun Life Bldg., Sherbrooke, Que.

How to Use and Operate Combustion Apparatus

The Following Article is Descriptive of Various Types of Combustion Apparatus Made by the Joseph W. Hays Corporation and Gives Explicit Directions for Their Use in the Power Plant

THE object of a flue gas analysis is the determination of the completeness of the combustion of the carbon in the fuel, and the amount and distribution of the heat losses due to incomplete combustion. The quantities actually determined by an analysis

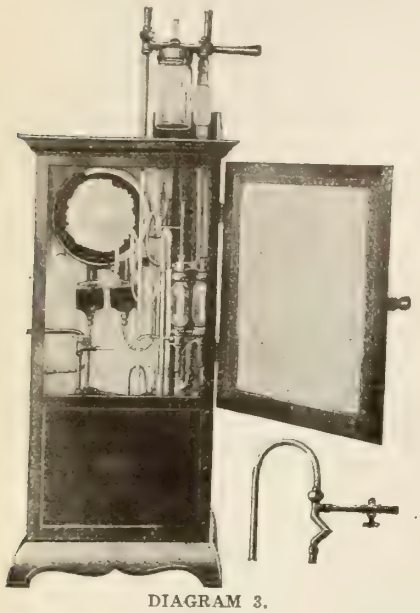

DIAGRAM 3.

are the relative proportions by volume of carbon dioxide (CO_2), oxygen (O), carbon monoxide (CO), the determinations being made in this order.

The importance of a constant record of the percentage of CO_2 in the gases of combustion cannot be over-estimated. The subject has been trimmed up one side and down the other, but to-day is considered one of the most important relating to the generation of steam.

The amount of steam generated depends upon the amount of coal burned per square foot of grate surface per hour, and the amount of coal burned economically depends upon a given draft that will release the maximum B.T.U. and burn the carbon to carbon dioxide (CO_2).

Therefore, in order to accomplish the economical combustion of the fuel we must have precise continuous record of what is taking place in the furnace.

There is some draft that will carry the load and produce the highest percentage of CO_2 without CO, and that is the draft to use at all times.

Engineers of to-day and to-morrow must become combustion engineers, instead of just engineers. The continual increase in the cost of fuel is making the plant managers the country over sit up and take notice. They are demanding to know just how their coal pile is being handled.

Some of these plant managers would not give the CO_2 salesman or the engineer a conference two years ago, owing to their ignorance of steam engineering, considering the boiler room of little importance and at that time coal was about half its present price.

Managers get together in their club rooms as do engineers. Subjects relating to proper operation of power plants are discussed. So it behooves the engineer to at least be on record, requesting instruments that will keep him posted, as his own plant manager is posted about the profit and losses of the business.

Every boiler should be equipped with a set of draft gages, one showing the draft over the fire, the other, showing the draft in the last pass. There should also be some means of recording or collecting your flue gases, keeping a daily record of same.

The first step should be to see that all excess air is eliminated, that your furnaces and grates are in good condition, and the boiler damper connected so that it can be operated from the furnace front.

The point at which the gas sample should be taken is in the centre of the gas flow, and at the point where the gases leave the last possible heating surface. A ¾-in. black pipe should be used, the end of which should be in the centre of the gas flow. An indicating or recording flue gas pyrometer

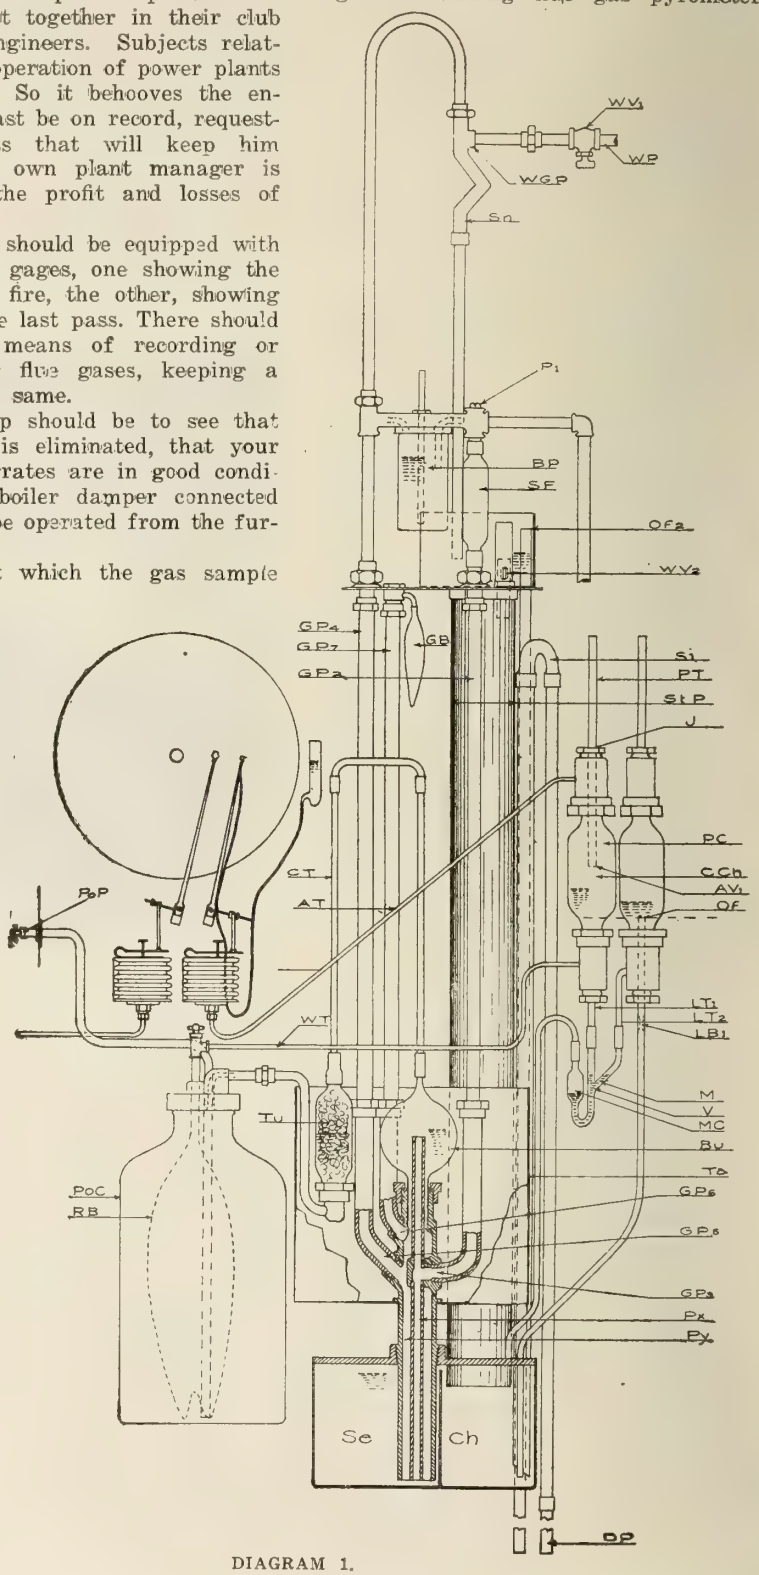

DIAGRAM 1.

should be provided, and the engineer will be prepared to get information as follows:

The percentage of CO_2 being produced is found, from which in turn we can compute the temperature in the combustion chambers. Knowing the temperature of the escaping gases leaving the boiler, it is possible to very readily determine the percentage of generated heat being absorbed, and from this information calculate the relative efficiency.

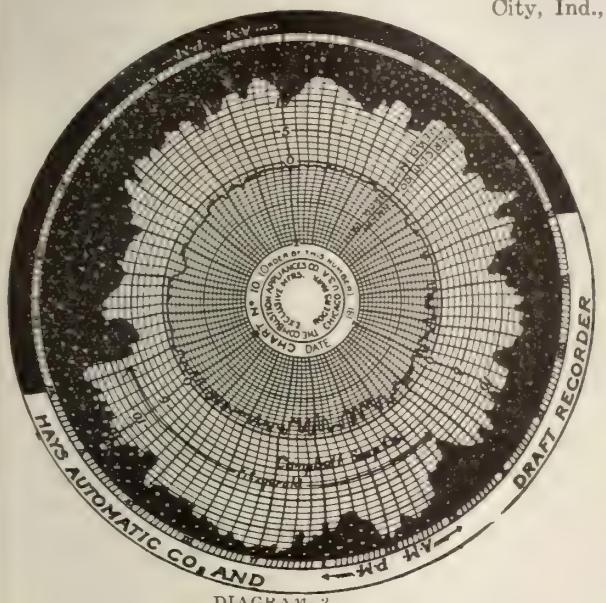

DIAGRAM 2.

The amount of CO_2 that will be the best to maintain depends upon individual conditions, but in general practice it will be somewhere between 12 to 14 per cent. The fireman cannot be expected to give the maximum B.T.U. out of the fuel unless they are provided with instruments to guide them. Many a fireman has been condemned on account of steam failures when he was in no way to blame. Firemen have been seen condemning the coal pile when it was difficult to maintain the steam pressure, but investigation proved that he was endeavoring to heat 300 per cent. of excess air plus the water in the boiler. After this very wasteful condition was eliminated the fireman was having things easy.

Don't be too positive that the excess air is not sufficient to hurt considerable. The engineer will be surprised when he finds out how small an opening it requires to admit sufficient air to lower efficiency to quite a degree. Leaks are bound to spring up in all boiler settings at any time, but with constant knowledge as to the percentage of CO_2 it will be possible to detect them at once, whereas, they otherwise exist and increase without the engineer's knowledge until expensive fuel bills arrive or a serious shutdown occurs.

In the analysis of combustion gases a great variety of mechanisms have been used at various times, and a number of different principles have been used in design. For the complete analysis of the gas recourse is usually had to the "Orsat" type of apparatus, while for boiler operation and the usual routine of the plant CO_2 records are usually sufficient. The indication of the amount by some means while useful is not so valuable as the recording of the varying percentage of CO_2 on a chart. The automatic CO_2 recorder, here described, is that manufactured by the Joseph W. Hays Corporation, Michigan City, Ind., and we are indebted to them for the material upon which this article is based and for illustrations which accompany it. The directions given for the operation of the different type of apparatus shown are all practical and since they apply to actual apparatus in service, more value attaches to them for this reason.

In the description which follows, the engineer is supposed to be present and listening to a description or a lecture on the various instruments and their operation, and by following the text in conjunction with the illustrations, the reader can very quickly gain an insight into the subject.

Referring to Diagram 1, the Hays automatic CO_2 recorder is operated by a jet of water flowing into the aspirator, WGP. The speed of operation is governed by the amount of water admitted through the valve, WV. The range of adjustment is from one to four minutes, but the most satisfactory chart will be produced at the rate of one analysis every two and a half minutes. By the inspirating action of the aspirator, gas is drawn in through the lines and secondary soot filter, SF. At the beginning of the operation the gas passes down through the glass tube GP2, through the burette, Bu, and out through the glass tube GP4, to the aspirator, WGP, where it is caught by the water flowing from the aspirator into the overflow tank, OF2, from whence the water flows into the standpipe, StP.

Both the measuring burette, Bu, and the absorption bulb, Tu. are immersed in water to insure uniform temperature. As the water flows into the standpipe from the overflow tank, the level of the water in the seal chamber, ScCh, below the burette and connecting tubes begins to rise and when it has risen sufficiently high to cover the tube traps, GP3, GP5, and GP6, the flow of gas is sealed off and a charge of gas is measured in Bu at atmospheric pressure. The flow of gas from the boiler continues, but is by-passed through the by-pass valve, BP. The water continues to rise in the tubes and in the burette, and the gas sample, which has been trapped off at atmospheric pressure, is pushed out of the burette through the connecting capillary tubes, CT, over into the absorption bulb, Tu, where the CO_2 gas is absorbed by coming into contact with the freshly exposed surfaces of the steel wool which is packed into the caustic or "absorption" bulb. The fibres of the steel wool are thoroughly wet by the caustic solution, which is forced out of the absorption bulb by the action of the apparatus. Inside the caustic chamber, PoC, is a rubber bag, RB, which holds a definite quantity of water and which is connected to the pressure chamber, PC, by means of a metal tube, WT.

When caustic is displaced from TU

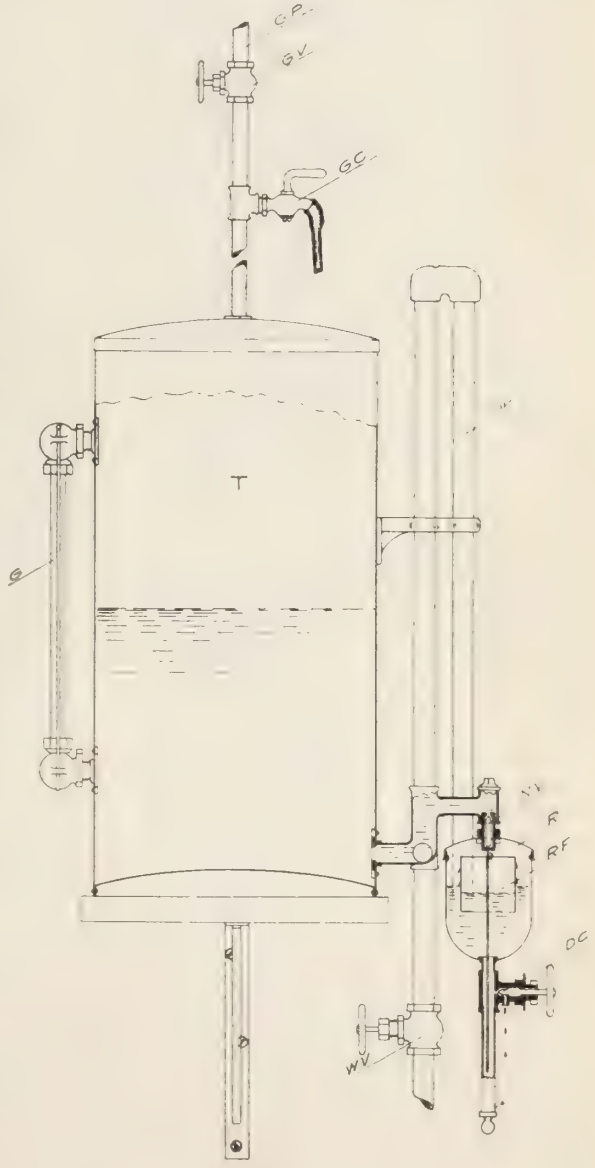

DIAGRAM 1.

into PoC, by the action of the apparatus, pressure is exerted upon the rubber bag RB, and water is displaced therefrom into CCh. Nothing happens until the rising water seals the lower end, AVl, of the tube PT, when the diaphragm with which PC is connected by the tube, AT, is expanded and the pen moves upon the chart of the recording gage.

The recording gage is so calibrated that if there is no absorption of CO_2 by the absorbing caustic solution the pen will travel entirely across the chart from the 20 per cent. line to the zero line. If any of the gases absorbed by the solution (which will absorb CO_2 gas only) the pen will not travel so far and the percentage of absorption will be recorded on the chart.

When the accumulating water reaches a predetermined height in the standpipe, the syphon, Si, starts, the water is discharged and the water and caustic return to their normal levels.

Adjacent to the compression chamber, CCh, is a levelling tube. The two are connected by the mercury valve, V. There is an "overflow," OF, in the levelling tube, connected by copper tube with the bottom of SeCh. The bulb of the mercury valve, MC, is connected with the top of SeCh. The arrangement is such that air pressure is exerted, on each operation upon the mercury in MC, thereby closing the valve, V, and water is forced from SeCh, up into the levelling tube. When the syphon, Si, discharges the mercury valve opens, making a communication between the levelling tube, and CCh, and as the result the normal level of the water in CCh is fixed by the overflow, OF. The levelling arrangement, which is a feature of this CO_2 recorder, enables the apparatus to make its own adjustments and to run continuously with very little attention.

These recorders are provided with "low efficiency alarms." A simple attachment causes a bell or series of bells to ring whenever the percentage of CO_2 is too low. Provided upon the same chart is a record of the draft which can be recorded from any point desired, same being calibrated for inches of water.

Diagram 2 shows reproduction of a Hays CO_2 recorder chart.

Diagram 3 shows the CO_2 and shaft recorder completely assembled.

Diagram 4 shows cut of this firm's automatic gas collector, which may be set up wherever desired, but in the preferred installation it will be placed upon a shelf about three feet high in order that the various valves may all be within reach of the operator. If convenient it is placed at the rear of the boiler. This will admit a short pipe connection between the flue or last pass of the boiler and the collector.

A connection is made with the cold water system of the plant, as shown, and a tight valve, WV, is placed on the water line. The tank of the collector is next about half-filled with water, and a pint of engine oil poured in at the top. The oil will act as a seal to prevent the absorption of gas by the fresh water taken into the tank.

Gas should be brought from the boiler to the collector through a quarter-inch pipe. Gas should be taken at the point where it leaves the heating surfaces of the boiler.

The valve, GV, is provided on the gas line near the collector, where shown in the diagram. The pipe connecting the top of the tank with the gas cock, GC, is furnished with the apparatus. This pipe is about eighteen inches long.

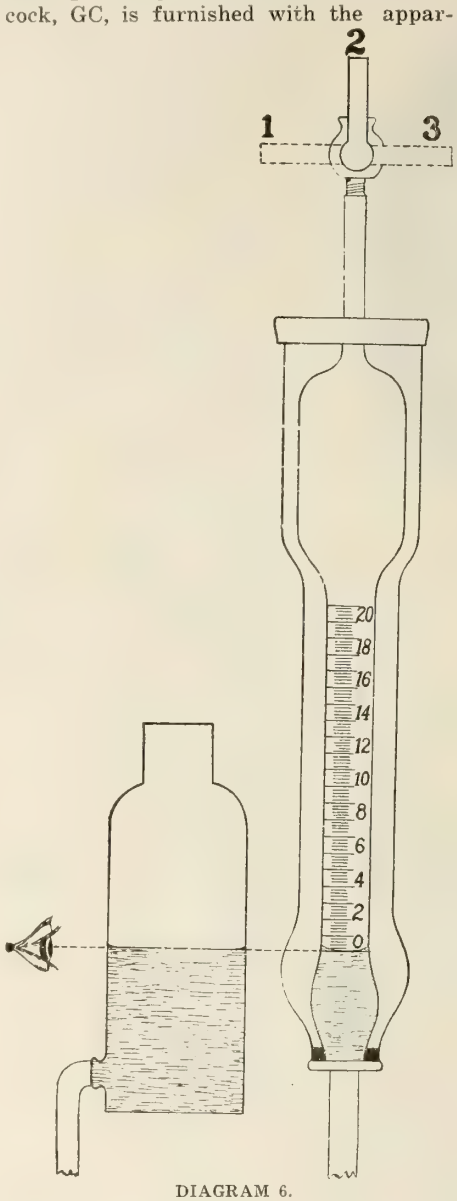

DIAGRAM 6.

All the connections having been made as above described, the valve, GV, is closed, the gas cock, GC, is opened, and the water turned on by opening the valve, WV. Should the water overflow through the overflow pipe, OP, before the tank is full, the plug of the gas cock, GC, is removed, and it is made sure that the opening is not stopped with grease or dirt. If there is no stoppage and the water continues to overflow through OP, before the tank is filled, the valve WV is closed gradually until the overflow ceases. The water must not be admitted to the tank faster than the air or gas can be driven out through the gas cock, GC. When the tank has been completely filled water will overflow through the pipe, OP.

The procedure is as follows when collecting a gas sample:

Having first closed the water valve, WV, and the gas cock, GC, the operator opens the gas valve, GV. Water will then flow from the tank, T, into the flow regulator, R, and be discharged through the drip, DC. The rate of discharge is constant without regard to level in T and will be proportional to the opening of the valve, DC.

The drip cock, DC, should be set to just about fill the tank with gas in the sampling period, whatever that may be. Analysis should be made at the end of each watch. The drip cock is provided with a dial and pointer. When the desired rate of flow has been determined by experiment, the position of the pointer is noted; thereafter the valve may be easily set for that rate at any time. It is not necessary to close the valve DC, after the collector has been put in service. In operating the collector it is necessary to use the valves WV, GV, and the gas cock, GC, the sample may be taken from the collector and the tank T, refilled with water without disturbing DC.

Assuming that the collectors have all been properly installed one on each boiler the chief engineer, head fireman or some one else who has been selected for the purpose next proceeds to the boiler room with the gas analyzer, and make an analysis of the gas trapped in each collector.

To analyze the gas that has been trapped in the tank, the valve GV is closed, the gas cock GC and the valve WV is opened. Water will flow into the tank of the collector and force gas out of same into the analyzer. If the water tends to overflow through OP, the leveling bottle is taken in the hand and lowered as far as the connecting rubber tube will permit. This will reduce the resistance. If the water continues to overflow, the valve WV is checked up. Gas should bubble out through the leveling bottle. When satisfied that enough gas has been passed through the analyzer to expel all the air from the connecting tube, and the burette, the rubber tube connecting the gas cock GC with the analyzer is disconnected, and the analysis proceeded with. (Instructions for the operation of the analyzer are taken up a little further in this article).

The tank of the collector will continue to fill with water, and by the time the analysis is finished water will be overflowing through OP.

If WV and GC are closed and GV opened, the apparatus will start at once to collect another gas sample. Gases when confined in a closed space will defuse and mix with each other. The sample in the tank of the collector will accordingly be uniform throughout.

Gas Analysis

A mixture of gases is analyzed by the "Volumetric Method," that is, a measured volume of the mixture is taken and one of the gases is removed by absorption. The volume remaining is then measured and the shrinkage indicates the percentage of the gas absorbed. The residue volume is then exposed to another absorber which removes another gas. On re-measurment the volume of that gas becomes known, and so on until all the gases have been determined. The volumetric method is employed because it is exceedingly difficult to weigh gases. If the weights are desired these can be easily computed when the percentages by volume are known.

Gases expand or contract very rapidly when subjected to changes of temperatures. The volume of a gas also depends upon the pressure to which it is subjected. For these reasons it is necessary that all measurements of volume during the process of analysis must be made under the same conditions of temperature and pressure. It makes no material difference what the temperature or pressure may be so long as neither is subject to change while the sample is being analyzed. The burette in which the gases are measured, is water jacketed. This controls the temperature. All measurements are made at atmospheric pressure by means of the leveling bottle.

Referring now to the illustration of the analyzer, and to diagrams 5 and 6, a tube at the right of the instrument case will be observed, having a scale from 0 to 21 etched upon it. This is the burette. The scale reads upwards from 0 to 21 per cent., and the divisions are in fifths of a per cent.

The burette is enclosed in a glass tube known as the water jacket, the latter being closed at the top with a rubber cap. The leveling bottle is attached by a rubber tube to the bottom of the burrette.

The instrument is stood upright upon a table and the leveling bottle removed from the clips (when in use in the boiler room or elsewhere, the instrument should be hung upon a nail using the hole in the back of the case near the top, the leveling bottle may then be hung by its hook upon the flanges at the bottom of the case, as shown in the illustration).

It will be noted that the instrument is provided with three absorber containers. The bulbs of two of the containers are packed with steel wool. The bulb of the third one is packed with copper wire and there is some scrap copper in the bottle below.

The container nearest the burette is charged with the absorber for CO_2 (a solution of caustic potash). The middle container is for the oxygen absorber (a solution of pyrogallic acid and caustic potash), and the one containing the copper is for the carbon monoxide (CO) absorber (an ammoniacal solution of cuprous chloride).

Preparing the Instrument

1. Fill the leveling bottle with clear water.

2. Note the three-way cock at the top of the instrument case, immediately above the burette. The cock has three positions, see diagram 5 and 6.

When operating the instrument you will stand on that side of it upon which the scale of the burette appears. When the handle of the cock is in a horizontal position, pointing towards you, gas can be pumped through the burette and will bubble out through the water in the leveling bottle. When the handle is in the vertical position as shown in the

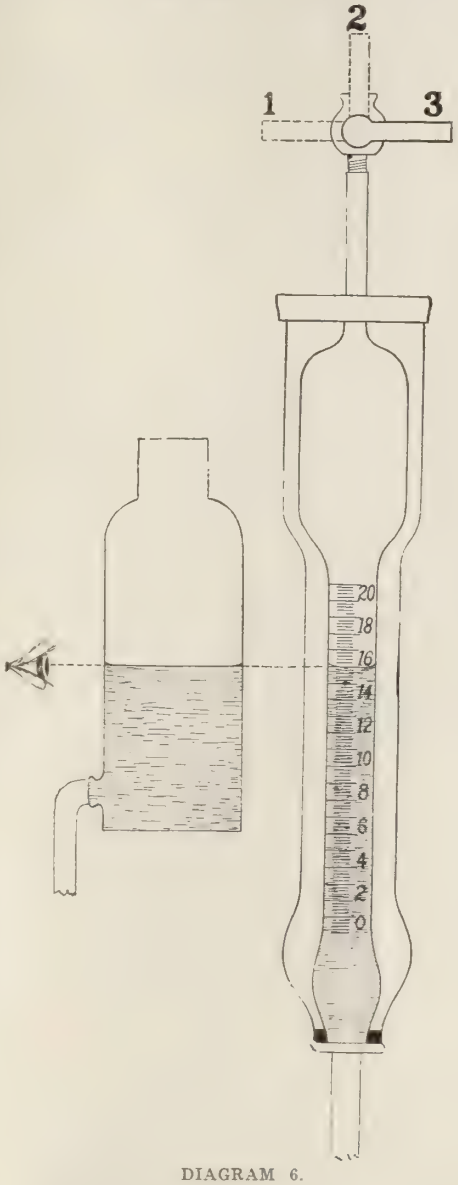

DIAGRAM 6.

illustration, the burette is open to the air, and when it is in a horizontal position pointing away from you, the cock is closed.

3 If the cock does not operate freely use a few drops of oil, applying it to the plug of the cock.

4. With the handle of the cock in a vertical position, raise the leveling bottle. This will cause water to flow from the bottle through the connecting rubber tube into the burette. The air in the burette will be expelled through the cock. Fill the burette in this manner until the water pinches out in the capillary tube at the top, then turn the handle of the cock into the horizontal position, pointing away from you. This closes the cock and if everything is tight the water will hold in the burette after you have lowered the leveling bottle. If the water falls in the burette turn the three thumb cocks of the needle-valves at the top of the instrument case to the right.

5. Lift the rubber cap at the top of the water jacket and fill the latter with clear water. Make sure that the cap is properly replaced after filling the jacket, otherwise the water will spill out when you are carrying the instrument. The water will last indefinitely as the cap will prevent evaporation.

6. Remove the stopper from the tube at the rear of the absorber container nearest the burette (the one for the CO_2 absorber).

7. Turn the thumb cock of the needle valve to the left and lower the leveling bottle. The caustic solution will be drawn into the absorber container. When the water reaches the bottom of the burette close the needle valve and raise the water again to the top of the burette, as described in paragraph 4. Re-open the needle valve and draw in the remainder of the caustic. When properly filled the caustic will stand in the capillary glass tube above the bulb and the container and will seal the glass tube in the lower bottle at least one-quarter of an inch. If there is not sufficient caustic add a little water.

8. The other solutions are introduced into their containers in the manner described in paragraph 7. The beginner is advised to become very familiar with the use of the instrument in the determination of CO_2 before changing the oxygen and CO containers. These solutions deteriorate on exposure to light and air. Keep the bottles stoppered and in a dark place.

9. In ordinary practice an operator will have little use for the oxygen and CO analysis. There is little danger of CO in the boiler furnaces gases when the CO_2 is less than 15. The first problem is to find the conditions that will produce 15 per cent. CO_2 and actually get that per centage.

Operating the Instrument

When this is done it will be well to learn whether CO is present.

10. Drive a nail in the boiler setting, or wherever is the most convenient, and hang the instrument upon it, opening both doors connect the rubber aspirator tube to the three-way cock and hang the leveling bottle upon the instrument case, as shown in the illustration. Be sure also that the caustic is standing in the capillary tube about midway and that the bulb of the container is full. It is possible that there may be some caustic in the capillary tube and that the bulb may be partially empty. In such case, partly fill the burette with air by lowering the leveling bottle, the handle of the cock be-

ing in position 2. Place the cock in position 3, raise the leveling bottle and open the needle valve. This will force the caustic out of the capillary tube into the bulb. Next close the needle valve and fill the burette with water, then open the valve and lower the leveling bottle (first setting the cock in position 3). This will draw the caustic up to its proper position. Be careful and do not draw any caustic over into the burette.

11. The aspirator tube is supplied with a filter, pack with cotton waste. This is to remove the soot and other foreign matter from the gas before it enters the instrument. The cotton should be changed from time to time. The aspirator tube is connected to the sampling pipe and the latter inserted in the last pass of the boiler.

12. Having connected the sampling tube, place the handle of the three-way cock in position 1 (see the diagram) and work the aspirator bulb. Gas will be pumped through the burette and will bubble out of the leveling bottle. Watch the bulb of the burette closely, and if there is any moisture in the gas (usually there is some) you will see it condense in a whitish vapor. When this happens you will know that you have pumped the air out of the tube, and are getting gas in the burette. You will soon learn about how much pumping it takes to get a fair sample of gas into the burette, this depends upon the distance pumped.

13. You are now ready to make a determination of the percentage of CO_2 in the gas sample that you have pumped into the burette. Now if you wish to learn how much chaff by volume there might be in a bushel of wheat you would first carefully measure out an exact bushel by volume of the mixed chaff and wheat. You would probably take a bushel measure, fill it heaping full and run a straight edge across the top of it. You would then remove the chaff and carefully measure the wheat. The steps that you take in making a gas analysis are exactly analagous.

You have gas in the burette but more of it than required. Take the leveling bottle in your left hand and hold it close to the burette steadying your hand against the instrument case. Get your eye into the position shown in diagram 1, and turn the handle of the three-way cock in position 2. Now, keeping your fingers on the handle of the cock, raise the leveling bottle until the water is on a level with the zero mark on the scale of the burette. Water will flow from the bottle into the burette and drive the excess gas out through the air vent of the cock. Keep the water level in the bottle in the same horizontal plans as the zero mark. To do this you will have to raise the bottle slowly as the water flows out of it.

You will notice that the water in the burette has a curved appearance. When the bottom of this curve, or meniscus as it is called, is on the zero mark, push the handle of the cock into position 3. You have now made an exact measurement of the gas and atmosperic pressure, and the gas is at the temperature of the water in the jacket.

Making the first gas measurement is the most "ticklish" thing connected with a gas analysis. You must not lower the leveling bottle while making the measurement as this would cause water to flow from the burette into the bottle and air would be drawn in through the vent of the cock. This would mix with the gas and spoil the sample.

Having made the measurement and locked the gas in the burette you will find that the leveling bottle is raised, that the gas is compressed, and the volume diminished, and that if you lower the bottle the gas is rarified and the volume increases. If you put the bottle on the zero mark the water in the burette will return to zero. This experiment should make it very clear to you how important it is to exercise care in making the original measurements and how necessary it is to make all measurements at atmospheric pressure.

14. The next step is to remove the CO_2 from the gas in the burette. Raise the leveling bottle with the left hand and turn the needle valve above the caustic container to the left. The gas will flow from the burette into the bulb of the container. Watch the water in the burette closely paying no attention to the container. You may push the gas over very rapidly until the water nears the top of the bulb of the burette, when you must slow it up with the leveling bottle and proceed very slowly. When the water pinches out in the capillary tube above the burette, close the needle valve by turning to the right. If you cannot pass the gas from the burette to the container it will be because you have forgotten to remove the stopper from the tube at the rear of the container. The gas has now been transferred to the caustic container and the caustic solution has absorbed the CO_2. The gas passes into the bulb over the fibres of steel wool which is wet with the caustic. The absorption of very rapid and you can immediately return the gas to the burette.

15. Open the needle valve and lower the leveling bottle. Pay no attention to the water in the burette. Watch the caustic closely. You may bring the gas back very rapidly until the caustic nears the top of the bulb when you must slow it up with the leveling bottle, and bring the solution up into the capillary tube.

Stop the solution about midway of the tube, being careful that none of it is drawn over into the burette.

16. Now bring your eye, the surface of the water in the bottle and the bottom of the meniscus in the burette into the same horizontal plane as shown in diagram 2, and read the scale of the burette (reading on the bottom of the meniscus). Let the water in the burette come where it will. Bring your eye and the water in the bottle into line with it. The gas is again at the temperature of the water in the jacket and it is at atmospheric pressure.

17. If for example, you find that the meniscus is resting upon the second mark above the 10 per cent. line. The reading is 10 2-5 per cent. Write it decimally, 10.4 per cent.

18. To take another gas sample for analysis, throw the handle of the cock into position 1, and work the aspirator bulb. The fresh gas will flush the stale gas out of the burette. A determination of CO_2 can be made every 45 seconds with this improved gas analyzer including the time taken to jump the gas into the instrument.

21. The absorption of oxygen and CO proceed very slowly and great care must be exercised in making the measurements. The solution used for oxygen will absorb CO_2 and that used for CO will absorb all three gases. For these reasons the CO_2 must first be taken out before trying for oxygen and the oxygen must be taken out before analyzing for CO.

20. To determine oxygen you first make a memorandum of the CO_2 reading and then pass the gas into the middle container, which you have charged with the pyro solution. Allow the gas to remain for about one-half minute, then return to the burette and measure, noting the reading. Return again to the container and repeat the operation until you get two readings that are the same. You then proceed in like manner to absorb the CO.

Suppose after the CO_2 absorption the reading is 16 per cent., after the oxygen absorption 20 per cent., and after the CO absorption 20.6 per cent. The analysis would be as follows:

CO_2 .....16 %
Oxygen ..... 4 % (20 % less 16%)
CO ..... 0.6% (20.6% less 20%)

Be sure that all of the CO_2 has been removed before trying for oxygen, and be doubly sure that all of the oxygen has been removed before trying for CO.

One exposure is all that will be necessary to get all of the CO_2 when the caustic solution is fresh. The solution will be good for about 500 absorptions. If you think that the solution may be getting stale pass the gas over a second time. If you get an additional absorption give the gas a little more time in the caustic container or change the solution.

The council of the city of Montreal, at a meeting held last week, voted a sum approximating two and a half million dollars for the purpose of completing the partly finished aqueduct for better water supply and the construction of a new low level pumping station. Two 30,000,000 gallon electric driven pumps, which will eventually be located in the new plant, have already been ordered and will be placed in the old plant pending the erection of the new building. With this equipment the capacity of the low level station will be about 140,000,000 gallons daily.

The Consulting Engineer in the Steam Plant

The Following Article Points Out Some of the Advantages to be Derived From the Retaining of a Consultant in an Advisory Capacity and Shows Where His Services Are Well Worth While in the Securing of Efficient Design and Operation

By F. A. COMBE

THE present high costs of fuel and labor have directed the attention of factory owners and managers towards methods of greater economy in power plant operation.

The possibilities of waste or economy are so immense, not only in the generation of steam but also in its utilization for industrial processes, that the subject calls for the most careful attention.

Lack of competent engineering advice on the initial design of the boiler plant is largely the cause of the inefficient way in which the majority of steam plants are operating to-day.

The practice of having a plant designed piecemeal by the different contractors supplying the machinery can be expected to produce only a composite lay-out which is extremely unlikely to give economical results.

In many industries waste material and waste heat may be employed to great advantage in place of coal, but their value depends on a careful study of each individual case and on correct design. The same is true of the possibilities of using oil, powdered coal, and the various lower grades of coal, coke breeze, etc.

These things should be taken into consideration when the plans are first drafted. Many of the older plants could be remodelled with advantage in view of changed conditions.

During the last few years considerable legitimate advance has been made in methods of efficiently burning fuels and in plant equipment for utilizing the steam thus generated. But unfortunately this advance has been accompanied by an influx upon the market of numerous inferior devices for which extravagant claims are made. Thus the owner or purchasing agent, if he is not an engineer is largely at the mercy of the most plausible salesman, whose main object, however conscientious he may be, is rather the sale of his product than the best interests of the purchaser. And further, the best equipment may not be the most suitable for a particular set of conditions.

It is a function of the consulting steam engineer to protect both the management and the operating force from such unsatisfactory equipment by giving an unbiased opinion on the best apparatus to be selected after an exhaustive study of the requirements and conditions, and from practical experience of the various apparatus offered.

Realizing the value of expert service in these matters, many of the larger corporations employ the services of a resident consulting steam engineer. The smaller firms who do not need the whole of such an expensive official's time, find it to their advantage to retain the services of a firm of practising engineers proficient in economical power plant design and operation. They rely on them not only to design new lay-outs and extensions, but also to act in an advisory capacity in connection with operation, to make periodic inspections and tests, and on this basis to suggest the institution of such systems and improvements as they may consider beneficial.

Unfortunately cases have been known where consulting engineers who are technical men without practical experience have made impracticable suggestions based on insufficient study of the plant and only partial knowledge of local conditions. Such reports are either paid for and pigeonholed, or, if acted upon, prove ineffective and a source of annoyance to the working staff, and so do more harm than good. This is particularly likely to occur when the consulting engineer is located at a point so far distant from the plant which he is supposed to study, that expense precludes anything but a short visit.

Such work should always be carried on in co-operation with the plant-operating engineer, not as a criticism of his methods but as a help to him as well as to the management. A progressive operating engineer will welcome a consulting engineer who knows his business and will work with him towards securing improvements. Usually he realizes very keenly that he is hampered by poor equipment and by lack of instruments and facilities to help him in obtaining efficiency. Almost invariably he feels that such handicaps make his work harder and less effective than it need be.

In addition to the recognized duties of other consulting engineers, which are to report on new schemes, prepare estimates, lay out new plant, issue specifications, recommend equipment and supervise construction, the consulting steam engineer goes further and deals with operation. Therefore he must be a man of peculiarly wide experience.

Not only must he be technically trained, but he must have practical experience also. He must be used to actual plant operation and the operating man's difficulties. He must have made a special study of furnace design, the combustion of different fuels, the utilization of refuse and waste heat—in fact of all that pertains to the economical generation and utilization of steam.

He should be constantly in touch with the latest practice and with changing conditions. He should know the value and limitations of various instruments and should have had first hand acquaintance with operating and bonus systems.

In addition, he must have analytical business ability to judge the value of expenditures from a financial point of view.

With these qualifications he will be of real assistance to both the operating engineer and the owner, and he will effect savings many times greater than the cost of his services.

ALCOHOL AS A MOTOR FUEL

Alcohol, which has been considerably discussed as the much-sought-for substitute for gasoline as a motor fuel, receives possibly more consideration than other proposed substitutes because there appears to be no limit to the possible sources of supply of alcohol.

The British Government, viewing with concern the rising price of gasoline, appointed a special committee to inquire into the production and utilization of alcohol as a motor fuel. This committee has recently submitted its report and we learn from "Power" that it found that while alcohol is obtainable from molasses, potatoes, wood pulp and other vegetable products, the yield, contrary to popular opinion, is not large.

The usability of alcohol in internal-combustion engines with a properly designed carburetor and slightly modified compression is well recognized, so that there is no obstacle from the engineering standpoint. It is purely a commercial problem. Owing to the somewhat lower heat value of alcohol a correspondingly greater quantity must be used per horse-power-hour, so that in order to compete with gasoline the cost per gallon must be proportionately less.—Houghton Digest.

ELECTRIC CRANES

In general design overhead electric cranes for engineering works have tended to become standardized, but a large British firm have introduced a notable departure which carries many advantages. Instead of the usual double-girder arrangement, giving a square appearance, there is a triangular girder, the apex of the triangle being downwards. This design gives a very rigid yet light girder and enables the load to be lifted one or two feet higher than would be possible with the usual type of girder. The driver also has a clearer view of the load from his "cab" than is otherwise possible. The firm has installed this new type in its own works and finds it most suitable for comparatively light loads on long spans—the very conditions which are least suited to the ordinary girders.

Enthusiastic—Sometimes

THE WHISTLE blew in a Toronto industrial concern a few days ago, as it has done for a good many years. There was more action in the next three minutes than there had been all day, with the possible exception of the noon scramble.

There was vim, ginger, push, pep — all these things and more — crowded into the few brief minutes following the tooting of the whistle.

A few nights ago young men started to line up outside the box office where tickets were going to be sold at 10 o'clock the following morning for a championship hockey match.

They stood in line all night and kept on standing until 10 o'clock in the morning.

There was surely perseverance, determination, and a keen desire to succeed in this demonstration.

But why is it that certain of us can pump up a heap more enthusiasm around quitting time, or over a hockey match, than over the great big task of making a success of our daily work?

Certain it is, were the same steam turned into business as was turned into the 5 o'clock quitting hour or the all-night stand for a hockey ticket there would be much greater successes and fewer people tossed out into the discard as very average or no good at all.

The Growing Scarcity of Anthracite

WITH anthracite at $17 a ton and even then with no assurance of adequate supply, the lot of Mr. Average Man will not by any means be an easy one during the next winter. If present indications are in any way reliable, they seem to point toward the gradual elimination of anthracite as a fuel for Ontario and Quebec and its replacement by some other fuel from domestic sources.

Apropos of all this, it is interesting to note that the "Canadian Mining Journal" in a recent issue published an exhaustive summary of the subject, going thoroughly into the available supply and also into the probable demand for the next few years.

The anthracite coal fields from which Canada obtains her supply are three in number, and while in some of these ample reserves appear available for a good many years to come, the cost of mining will make anthracite an even more expensive luxury. It is estimated that thirty years will see a decline in the production of the Wyoming field, and since this field supplies the major portion of Canada's requirements, a corresponding stringency in our supply.

The growing scarcity of hard coal is already starting a search for suitable substitutes and of these coke and oil would seem to be the most feasible for domestic use. The use of these in turn would make Central Canada dependent on a foreign source of supply to a large extent and would in turn leads to periods of scarcity and fuel famine.

The burning of briquetted Western lignite would be perfectly feasible, although the long rail haul would be expensive. The peat resources of Ontario and Quebec will undoubtedly be of high value when the necessity for their use has been fully appreciated.

In the meantime the householder in the central provinces will have some interesting scurrying to do in the getting in of his winter's supply. Not only so, but it may prove to be the golden opportunity for some enterprising manufacturer in the developing of an economical and cleanly method of burning other forms of fuel in the house.

The Small Waterpower

THE VALUE of the smaller waterpowers of the country is well brought out in the leading article of this issue. The development, while small in comparison to Niagara, is yet of sufficient size to furnish ample power for the operation of a large textile mill, and by good design and operation very economical power is available. The combination of power plant, transmission line and substation is particularly worthy on account of the excellent care with which the work has been carried out and the manner in which the various parts have been fitted together.

The installation mentioned serves to point out the value of the smaller waterpowers in the industrial development of their immediate neighborhood.

Doctoring Our Lignite

CANADA has had enough coal experience in the past two or three years to make the nation stop and think. The trouble with these stopping and thinking seasons is that they are brief and evaporative.

When we are up against the real thing we stop and think and promise.

When the real thing has been removed, we at once forget about the stop-think-and-promise session.

That is what happens to the average Canadian in regard to the coal supply of this country. As soon as he gets a supply, or as soon as his fire is out for the summer, he proceeds to forget it.

The industrial section of Canada is more apt to remember the problem, and for this reason should appreciate the work that is being undertaken by the Lignite Utilization Board of Canada. Industrial sections are interested in domestic fuel as well as in power and heating provision. If the employees can get only a little coal, and pay a very high price, they are going to be dissatisfied and the firm employing them suffers.

The Lignite Board for the present is chiefly concerned with the deposits of lignite in Saskatchewan and Alberta, although Saskatchewan would be the more strategic point from which to work, either east or west. The order creating the board says in part:

"That by carbonizing this lignite, a coke or charcoal is obtained which briquettes readily and, without consideration of the by-products such as oil, pitch, ammonia sulphate, gas, etc., the result is to turn two tons of inferior fuel into one ton of briquettes approximating, in heating value, anthracite coal with practically the same heating value in the domestic furnace as the two tons from which it was made."

A study of machinery, processes, etc., for briquetting this coal is being made, and the matter of using any other by-products will be considered.

Western Canada has heretofore imported about 500,000 tons of anthracite from Pennsylvania at a cost of about $5,000,000 per annum.

Canada's coal resources are greater than those of any country in the world, with the exception of the United States. Much of Canada's coal, however, requires treatment before being available for satisfactory domestic use.

It is expected that a successful outcome of the development undertaken by the board will result in the establishment of an industry of national importance.

The Smallest Screw Made

DURING wartime we heard much of working to fine dimensions. People who used to romp around the shop with a foot rule and measure eighth-inches only in a pinch began to think and measure in terms of thousandths.

A writer in a current magazine speaks of the smallest screw used in the smallest watch made in this country.

Now put down your monkey wrench, screwdriver, hammer and can opener, step over and hear what is said about this screw:

It might be possible, under some conditions, to hear the proverbial pin drop, but no ear could catch the sound of the dropping of one of these screws.

The screw can be definitely seen only with the imagination or a watchmaker's glass. This tiny screw is of brass, of the following dimensions:

Total length, 28 thousandths of an inch.
Diameter of head, 26 thousandths of an inch.
Diameter of the thread, 12 thousandths of an inch.
Number of threads per inch, 360.
Weight, 12 thousandths of a grain.
It takes 583,333 of the screws to make a pound.

The machines for producing these screws are different in design from any other screw machine that is known of. They are of a positive cam action type and have proved very satisfactory to their users.

There is but one chuck to a machine of this type and a single piece of stock is used. These machines are so accurately made and the parts so closely fitted together that it is necessary for them to be warmed up in order that the oil may work in all of the bearings before they start to produce. Otherwise they would not operate.

The machine is belt-driven. Compressed air is used on these machines for the purpose of forcing oil to the different parts of the machine and also to blow out the finished work after it has been cut off. These machines are electrically controlled and are so arranged that they stop whenever the stock is used up or the finished screw not blown out of the machine.

Is Good Design Worth While?

IT IS often a question in the power plant owner's mind whether money spent on fixing up a power plant, on things from which no immediate results may be obtained, or in the improving of the plant appearance, is worth while. The power plant, it goes without saying, should be one of the neatest and cleanest portions of any industrial works or other concern, and money spent in the initial stages of its design will be well repaid later on if by its means the plant can be kept and maintained in better shape. For a power plant in trim condition is most likely a well managed and economical one, and in the long run neatness and efficiency go together.

A MAN who likes variety can surely get it by thumbing over the pages of the seed catalogue after shaking down the furnace for the evening.

TOMBSTONE carvers in some United States cities are asking $1 per hour for their work. So it will pay more than ever to build each day such a monument in the minds of your associates that the work of the stone cnippers will be unnecessary.

From "Passing Show," London.

CRUEL TO BE KIND

Lloyd George:—"Hold your noise! I've brought you here to enjoy yourselves, and enjoy yourselves you shall."

Progress in New Equipment

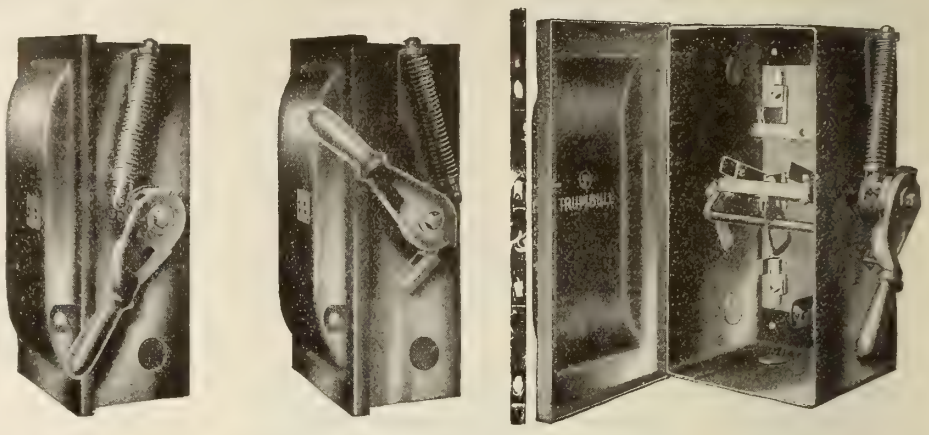
"SAFETY" SWITCHES

THE "safety" switch is one of the ramifications of the safety movement that has gained such tremendous headway in the last few years. It is common sense to prevent accident to life and property, because it is a matter of human decency and because it is a paying investment. The proper safeguarding of points where accidents are liable to happen and the proper protection of mechanisms, which in themselves are potential danger hazards also, means better insurance rates and fewer law suits. Industrial plants are pretty well in touch with the situation, having learned through real experience the need to protect life and property at every turn of the wheel. They do not think so much in terms of first cost as in terms of safety and the secondary expense of accidents.

One of the hazards to which attention was early drawn was the open knife switch, and to-day these are almost a thing of the past, insofar as industrial plant applications are concerned. It is now customary to enclose switch and fuses in steel boxes, so arranged that switch operation is possible from the exterior.

A switch externally operated may suggest to a man that he should throw off the switch before he puts his hand in the box, but an interlocking safety device, which prevents his opening the box until the switch is off makes him keep his hands away from live switch blades.

This latter accident prevention feature has been developed by the Trumbull Electric Mfg. Co., Plainville, Conn., in a line of externally-operated switches recently placed on the market.



SAFETY SWITCH SHOWING MECHANISM.

By reference to the accompanying illustrations a very good idea of the arrangement of these switches may be gained. The box cannot be opened until the switch is in the off position. A catch prevents the switch from being closed with the box open, although the catch can be manipulated by a tool if necessary to close the switch with the box open for inspection, by an experienced man. It will thus be seen that with fuses and blades always dead whenever the switch is exposed, the fire and shock hazard are eliminated.

All single throw switches are equipped with an outside handle stop as a means of indicating when switch blade is in full contact. A further advantage is seen in the fact that the switch can be locked open.

There is a growing demand for a safety switch with quick make, as well as quick break, particularly where a careless operator might neglect to follow the handle through and so leave the blade in partial contact with the jaw post. The switches shown in our illustrations are equipped with this feature. A further device is seen in one of the types illustrated where a "100 per cent. safety shield" is shown. This is a further protection to the operator or electrician when the cover is open for fuse replacement.

VIEWS SHOWING SAFETY SWITCH OPEN AND CLOSED AND WITH COVER OPEN SHOWING 100% SAFETY SHIELD.

THE "MATTER WITH AMERICA"

What's the matter with America these days?

Too many diamonds, not enough alarm clocks.

Too many silk shirts, not enough blue flannel ones.

Too many pointed-toed shoes and not enough square-toed ones.

Too many serge suits and not enough overalls.

Too much decollete and not enough aprons.

Too many satin upholstered limousines and not enough cows.

Too many consumers and not enough producers.

Too much oil stock and not enough savings accounts.

Too much envy of the results of hard work and too little desire to emulate it.

Too many desiring short cuts to wealth and too few willing to pay the price.

Too much of the spirit of "get while the getting is good" and not enough of the old-fashioned Christianity.

Too much discontent that vents itself in mere complaining and too little real effort to remedy conditions.

Too much class consciousness and too little common democracy and love of humanity.—Fargo S. D. Forum.

Re the Ontario Graded Certificate Act

Correspondence

DOES THE ACT HOLD THE GOOD MAN DOWN?

This correspondent argues that as the man deserves so shall he be rewarded, and that the Act in itself does not limit his scope for employment nor does it force him to remain in whatever plant he may happen to be in.

The Editor.

I have been reading the letters re graded certificates that have appeared in the POWER HOUSE for some months past with increasing interest. In Feb. 5 issue, James Scotch says: "Forcing the second and third class men to stick to small plants is the one big injustice." I don't see that the law forces anybody to stay anywhere. Have we not got to rise mainly by our own efforts? If not, who will be the first to give the helping hand? The profession of engineering cannot be learned in a day, nor a year, nor 5 years. To quote Ella Wheeler Wilcox: "The fault of the age is a mad desire to leap the heights that were made to climb." In Feb. 20 issue, Justice II gives a good practical letter. What was wrong with 55 out of the 60? Were they confident and prepared to hold a better position? With what did they expect, then, to hold it? not air and daylight.

Some men rise by years of hard work and close application to study and details. Others rise (or attempt to), by knocking others down. Others, when they do get up there, promptly kick the ladder away, so to speak, so that none may equal them. Last two are knockers and soreheads, and there are lots of them. Envy, the enemy of progress, always seeking to destroy what it can't equal, let alone surpass.

These seem to me to be the lines along which a lot of men are working, and they are not good lines for anybody, especially engineers. Just forget petty jealousies, and work, study, live and let live. There is always lots of room at the top.

"HORATIO."

THE WORD "WOP" IS UNFORTUNATE COGNOMEN

While engineers are blessed with various degrees of book knowledge, the present writer argues that nothing is to be gained by calling those with little theory by derogatory names.

The Editor.

I notice in your issue of Feb. 20 a letter from James E. Noble and wish to say that I agree with him to a word as to size of power plants to be operated by the different grades of engineers. I also agree with his suggestion as to the first class certificate, but I wish to take exception to his remark regarding the man he calls a wop. I myself have only a public school education and I could not possibly pass the required examination for a first class certificate without undertaking a further course of study. Yet I can operate the boiler room efficiently and with the minimum amount of coal, and, taking my indicator, can set my valves as correctly as James E. Noble, or anyone else. So I do not consider myself a wop and I do not think the above term is one that can be used in connection with a good many engineers who are unable to qualify for the first class certificate.

Another thing I wish to say is, theory and practice do not always go together. This is a fact known to any practical engineer. As an instance in point, take the following: During the present winter I have had under my charge a boiler feed pump of well known make. The same was receiving hot water from an overhead tank and was in first class condition, yet it would not feed the boiler. There was no obstruction in the delivery since an injector was feeding through the same line. The pump was made to work successfully by the writer in about three hours' time after it had failed. Let the theoretical man tell me what was the matter. The question will be easy enough for the practical man.

I also wish to say a word or two in reply to Chief. He states in one of his letters that at the time certificates were first granted, any old hole was good enough for a man to qualify in and obtain a certificate. He thinks that an old-timer should be granted a first class certificate without any writing for it. Is he looking for a chance like the one above, which he intimates was the case when he obtained his first certificate. Like Justice II, I think the examiners are going to call the bluff of a lot of our chiefs. I did not intend to be sarcastic, but reading some of the letters some things are bound to get under one's skin, no matter of how mild a temper he may be. I hope to hear some more good-natured grumbling. WM. H. LONG.

THE STATUS OF THE STATIONARY ENGINEER

IT has been said "If a man can do any one thing better than anyone else, the world will wear a beaten path to his door, no matter how deep in the woods that door may be located." Have the stationary power plant engineers considered and thought about this saying as they should? Is there any truth in the saying? Personally I believe it has been proved beyond controversy.

If this is so, is it any wonder the operating engineer always has been and always will be counted or considered as "small potatoes" no matter how large or how small is the plant he has charge of. The operating engineer is a jack of all trades; to become a specialist in any one of these trades requires many years of practice and study. It requires no superfluity of brains to understand that not one man in a million can be an expert in a large number of mechanical trades and professions; a man with a smattering of each—which closely describes the best class of engineers in charge—is nothing greater than an apprentice in any one of them, therefore he gets the credit and honor due an apprentice and nothing more. When the time comes that engineers generally will recognize this truth and work for conditions which will enable experts to be in charge of different parts of the plant the engineer will then take a limelight position in the world's view. Take the electrical specialist. He is honored, respected, and highly paid for his advice and services. Ask him about line shaft installation, steam-heating, superheating, or one of a hundred other things the power plant engineer has to erect, instal and control. He will probably say: "My dear sir, I am an electrical specialist; I prefer not to pass any opinion upon subjects outside my special line." He is perfectly right at that. Probably he knows about these things but he is not taking chances by giving advice upon matters about which he is only partly informed.

During an analysis of salary problems which occurred in a public utility hearing, the point was brought out that the assistant superintendent received a yearly salary exceeding that of his superior. As the manager explained, the assistant happens to be a specialist, therefore he is entitled to extra pay for his superior knowledge. When the boiler room is placed under the responsible charge of one man, the engine room under specialists, steam and electrical, and the shafting and other machinery under properly trained men, each and all being directly responsible for the operation and condition of the equipment in their charge reporting direct to an executive head, such as a manager, then the power house staff will begin to receive some honor and respect. No doubt the plant costs for labor would be greatly increased, due to the extra remuneration received by the specialists in charge, but the increased production, elimination of plant waste, the absolute absence of danger so far as humanly possible, and such like important matters, would many times overbalance the extra cost in salaries. So long as the power plant operator has to prove that he is a "jack of all trades" by passing such a mixed examination as he is doing to-day in many places in Canada and the United States, just so long will he remain in the background.

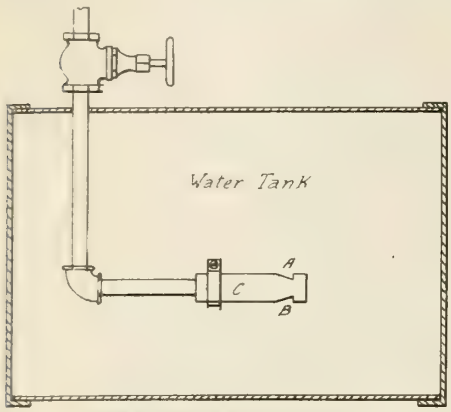
J. E. NOBLE.

The Operators' Point of View

NOISELESS WATER HEATER

I am enclosing a few more simple ideas that I use or have used. I expect every engineer has heard about the noiseless steam-water heater, however. Some of of them do not know how to make one, if a person is to form an opinion from the racket heard in some places where they are heating water with live steam.

A short piece of hose, a jack knife and a hose band is all that is required. In Fig. 1, C is the hose. Cut two pieces from the hose, as at A and B, fasten the



NOISELESS WATER HEATER.

hose to the steam pipe, that's all. Iron pipe will do instead of the hose.

Often when an air cock is wanted in a hurry there is none at hand. Take any sized bolt, file a groove in it, as shown in Fig. 2, place a rubber or fibre washer under the head, as shown in Fig. 3 at A. Screw the bolt down into the air cock hole. When it is necessary to let air out unscrew the bolt a turn or two. Fig. 4 shows a bolt with a hole drilled up the centre and through the side, a washer is also used under the head of this bolt. When it is necessary to let air escape the bolt is unscrewed until the small hole at the side comes up to the atmosphere side.

The proper way to grind cold chisels is shown in Fig. 5. Most fellows grind their cold chisels as shown at A. Next time grind them as at B, and note how much more service can be got out of them without breaking corners off. The convex shown is rather exaggerated to show the idea plain. The edge should be only slightly off the true, also have one of your chisels ground as at C, for a close cut it is just the thing, and be sure and have a bent chisel as shown in D; this one is for difficult corners. It sometimes helps to have this chisel ground the same

C. JOHN PORT.

CONVERTING A BREAST DRILL INTO A DRILL PRESS

By W. S. Standiford

One of the most useful devices that every mechanic or experimenter has in his home workshop is a breast drill. The drawbacks of this instrument are that it has to be held very carefully if a straight hole is to be bored; and also that it requires considerable "brute force" to make the drill feed into the work. After using a breast drill in the usual manner for a number of years, the writer decided to convert it into a drill press, and thus make it not only easier to operate, but also to do more accurate work than a drill pressed against the body is capable of.

The photographs show the general construction clearly, no dimensions being necessary, as each breast drill made varies so in size that the construction will have to be made to suit the user's instrument; the only thing to do is to follow the shape as depicted in the photographs. Fig. 1 shows the completed apparatus ready for a drill to be inserted. It will be seen that the feed is automatic, it being done by gravity when using a 1-16 inch drill, but wide rubber bands are used to assist the weight of the drill rack and round bar iron weight when larger sizes are used. The bands are put on the projecting lower ends of drill rack (only

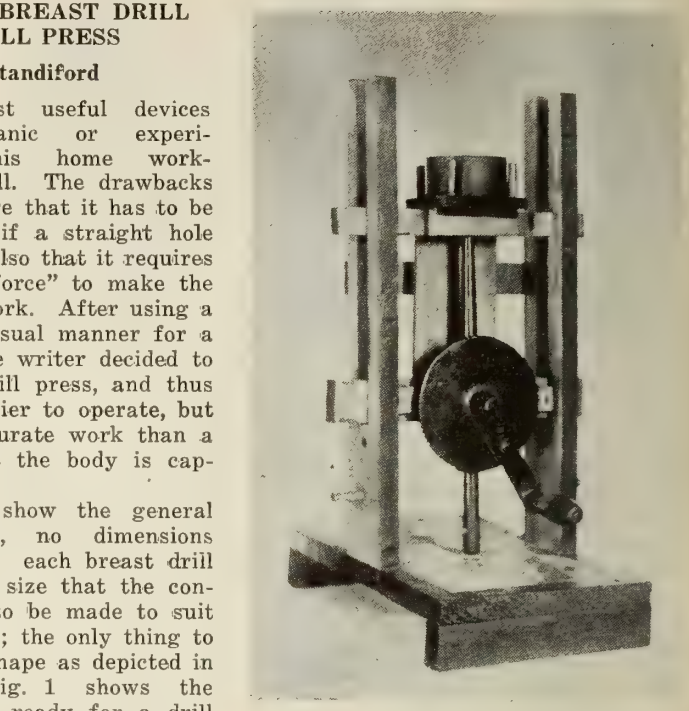


Fig. 1

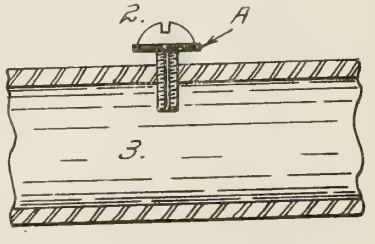
side being shown in the photograph) and a round pin on the sides of the standards. As this press has been in use for a number of years, using rubber bands, the writer intends to replace them with closed-coil springs fixed to



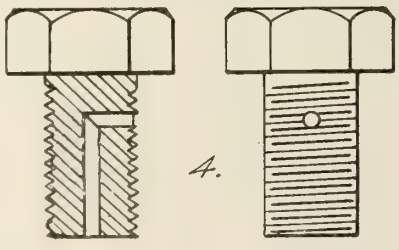


FIG. 4.

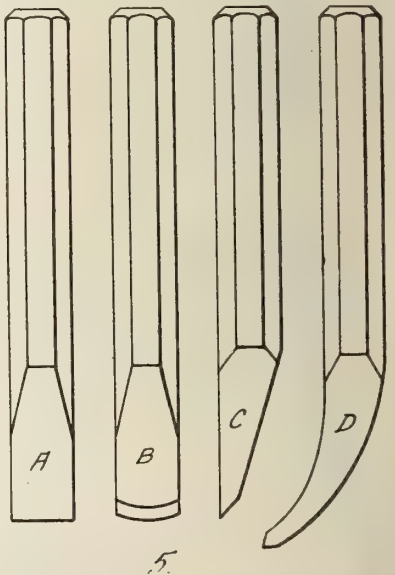

FIG. 5—METHOD OF GRINDING COLD CHISELS.

a hinge on their lower ends, so as to be disconnected when the press is used for boring small holes, as too speedy drilling dulls the drills quickly. Closed-coil springs are better than the rubber bands when working with larger drills, as more pressure can be obtained, the amount depending upon the diameter of the wire thickness in the springs.

Fig. 2 shows the standards with the drill rack out, while Fig. 3 illustrates the rack itself, the round bar iron weight being removed from its retaining prongs. The upright wooden standards should be made out of hardwood and have the slots that drill rack slides in carefully made and fitted to the former, so as to have just enough play to let it slide freely up and down. Rub dry graphite on the bearing parts of standards every once in a while, so as to get the wood saturated as much as possible. Use a square when fastening standards on the baseboard. Put cleats upon the cross bars of drill rack, so as to prevent any side play, thus insuring that the holes bored will be straight. This apparatus will be found to give good service in the home workshop, mine being in use over ten years. It is still in good condition, with the exception of the rubber bands, which occasionally get hard and lose their elasticity; the latter being restored by soaking them in kerosene oil. I would advise any other constructor to use closed-coil springs, as it is a nuisance to be fooling with rubber bands. Closed-coil springs will give no trouble.

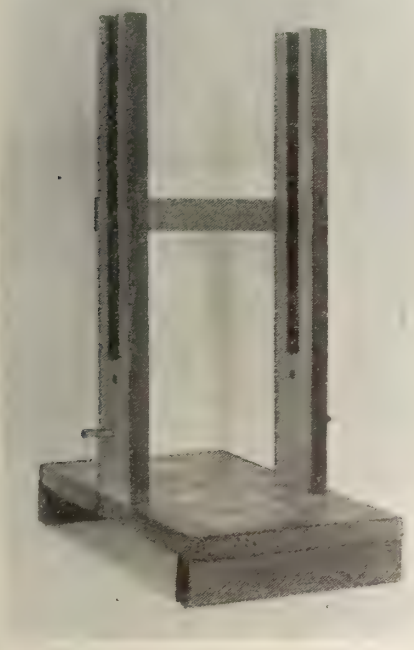

FIG. 2.

LUBRICATING OILS
A New Theory

Ever since the introduction of mineral oils for lubricating purposes, it has been recognized that their behaviour as lubricants is markedly inferior to that of the animal and vegetable oil. In virtue,

FIG. 3.

however, of their cheapness, and in some instances of their non-emulsifying qualities, they have come to play a largely preponderating part in the lubrication of machinery. The defects of pure mineral oil as a lubricant have resulted in almost all commercial lubricating oils containing an admixture of some organic oil of animal or vegetable origin, in order to give them the necessary physical properties. The organic oils in practice, however, always contain, even when highly refined, a certain proportion of what are known to the chemist as "fatty acids." These weak organic acids, because of the fact that they are acids, have always been looked upon with the greatest distrust as components of a lubricating medium, and the maximum permissible amount has been the subject of rigorous specification.

From a paper on lubrication read before the London section of the Society of Chemical Industry by Messrs. H. M. Wells and J. E. Southcombe, it would appear that these much distrusted fatty acids play a hitherto unsuspected part in the process of lubrication and may almost be considered essential factors in it. This view, which appears to be confirmed by practical experiments on a commercial scale, is not only interesting scientifically but of material practical importance. If, as appears, it is the fatty acid and not the organic oil as such which gives to a compounded mineral oil its lubricating qualities, the recognition of this fact will result in rendering available for human consumption and other purposes vast quantities of edible animal and vegetable oils now used in the lubricating oil industry.

Surface Tension

The discovery by Messrs. Wells and Southcombe was the outcome of experiments undertaken to determine the factors on which the lubricating value of an oil depends. Ultimately the conclusion was arrived at that surface tension is the dominating factor, and as the surface tension between oil and a solid surface is not measurable by any known means, the authors decided to measure the surface tension of oil in contact with an immiscible liquid. It is difficult to admit the logic of the conclusion that oils in contact with metal should behave in the same way as when in contact with water, nor is it very easy to see what bearing the behaviour of oil and water has upon lubrication. However, when various kinds of oil were allowed to rise in drops from an orifice submerged in water, a marked difference was observed between the behaviour of organic and mineral oils. It was brought out clearly that the inter-facial tension, which is inversely proportional to the number of drops into which a given volume of oil would divide itself, is very much less in the case of the organic oils than in that of the mineral products.

Thus a difference between these two classes of oils has been discovered, which is independent of viscosity, density, etc., and, moreover, appears to be in conformity with the lubricating qualities of the oils. The next step was to find the reason for the difference in surface tension, and it was eventually proved that the slight quantity of free fatty acidity present in the organic oils is the cause of their reduced surface tension. When the fatty acids were removed the tension rose, and when they were added it became lowered. However carefully ordinary commercial organic oils are purified there is always a small amount of free fatty acid present in them, as hydrolysis sets in and produces such acids in a short time. It is to the presence of small quantities of these acids that, in the opinion of the authors, the superior lubricating qualities of the organic oils are due, and by adding a very small percentage of such acids to mineral oils they have improved the lubricating properties to the same extent as if a very considerable bulk of organic oil had been added.

Effect of Fatty Acid

Figures were given by Mr. Archbutt in the discussion on the paper which showed how powerful is the effect of a very small quantity of fatty acid. He used a Thurston oil-testing machine to carry out the experiments and worked it with a journal speed of 7 ft. per second and under a pressure of 270 lb. per sq. in. Under these conditions he found the frictional coefficient of pure mineral oil to be .0066, and the effect of adding free fatty acid up to 2 per cent. is shown by the following table:

Percentage of mineral oil	Percentage of fatty acid.	Coefficient of friction.
100	0	.0066
99.5	0.5	.0049
99	1.0	.0045
98	2.0	.0042
100	0	.0066

The effect of adding rape oil, from which all trace of fatty acid had been removed by treatment with lime, was next exemplified by Mr. Archbutt by the following figures:

Mineral oil.	Rape oil.	Coeff. of friction
100	0	.0066
90	10	.0065
80	20	.0062
60	40	.0053
40	60	.0047
20	80	.0041
0	100	.0045
100	0	.0062

In each case the last test given in the table is a check test to verify the conditions.

It will be seen from the first table that only half of 1 per cent. of free fatty acid added to pure mineral oil causes a very marked improvement in its lubricating power, and that 2 per cent. appears to be about as much as it is advantageous to use. Comparing the two tables it will appear that the effect of adding 1 per cent. of free fatty acid to a pure mineral oil improves its lubricating qualities fractionally more than the addition of 60 per cent. of neutral rape oil. This is a very striking result, and appears to justify the contention that the lubricating qualities of the organic oils are very largely dependent upon the free fatty acid which they contain. The natural corollary is the manufacture of lubricating oils by the addition of fatty acids to mineral oils, and this is being carried out on a commercial basis by the inventors. The process was patented about two years ago, but publication was forbidden by the authorities until after the war. However, the Admiralty accepted large quantities of marine engine oils made by the process, for duties for which a compounded oil containing 20 per cent. of rape oil was previously considered essential.

Physics of Lubrication

The scientific interest of the matter lies in the light it may shed on the ultimate physical mechanism by which lubrication is accomplished. The very small quantity of fatty acid which brings about the results seems to indicate that some absorption process may be at work, the fatty acid molecules attaching themselves to the metallic surfaces and in some way altering its condition. The acidity may be necessary for the purpose of producing some metallic salt on the faces of the bearings, the presence of which causes a reduction of friction. Many other speculations may be advanced, for the matter is very obscure; yet it is something to have got a little farther with the empirical solution of the problem of lubrication, even if the underlying theory is not elucidated.

EFFECT OF HYDROGEN ON IRON AND STEEL

German technologists have continued their researches since the armistice, one of these being the effect of various gases on iron and steel. The results suggest, says the London "Ironmonger," that if the gases could be conveniently and safely applied, some of them, and particularly hydrogen, might be employed with advantage in certain metallurgical operations, as in the cementation process of making steel and in refining and hardening. The use of hydrogen with iron at high temperatures, however, unfortunately is difficult and dangerous, apart altogether from its high cost, and it is not likely therefore that it will be used for any of these purposes on any commercial scale, though it may continue to be used for research. When that gas is forced through molten iron it is found that any non-metals present such as arsenic, carbon, phosphorus, silicon, sulphur or oxygen are converted into gaseous hydrides while the hydride itself in any particular case may be split up again and the nascent hydrogen set free, under which conditions it will reduce any silica present in the metal, even at so low a temperature as 1,292 deg. Fahr., the gaseous silicon hydride resulting.

From the practical point of view the most interesting of the results of this particular research lies in the revelation that a malleable iron may be made directly by means of oxygen and hydrogen, not only from molten iron but from solid pig. The inert character of nitrogen is confirmed by this research, that gas having no effect on the non-metals in iron, either in the solid or liquid state, notwithstanding the view very generally held that the carbon in iron will diminish if the metal be heated in an atmosphere of nitrogen, the real explanation of this diminution being the action of small portions of oxygen retained in the vessel with the nitrogen.

EDMONTON CONTEMPLATES NEW ELECTRICAL SYSTEM

At a meeting of the Edmonton city council held on March 9, the following resolution was passed:

> "That the City Commissioners do immediately invite proposals from such persons or companies as have signified a desire to negotiate to supply power to the said City of Edmonton, and that such proposals should contemplate the bringing up of our present power plant to a proper standard of efficiency and installing of a further unit of agreed capacity and type; and that the commissioners do at the earliest possible date report to this council a general outline of the respective terms and conditions upon which such persons or companies would be prepared to supply power,"

and referred to the city commissioners, and at a subsequent meeting of the city commissioners, the question dealt with in the resolution was referred to Joseph A. Clarke, mayor, for such investigation as was directed by the city council.

It is stated that whatever rights the Edmonton Power Company have under their agreement or franchise with the city, must be considered by any person or company making a new offer to the City of Edmonton. The suggestion was made that the Edmonton Power Company would surrender their franchise, and probably also sell any work or development that they have already undertaken, but this would have to be considered by any who are making an offer to the city to manufacture power as set out in the resolution of council above referred to.

The power house is not equipped at present with machinery enough to supply all the electrical energy which is required for the customers of the City of Edmonton and the city is now submitting a by-law for the purchase of another unit, which will be either of 7,500 kw. or 5,000 kw. capacity. The by-law is being submitted for approximately $700,000.

If any scheme is suggested which contemplates anything in the nature of a hydro-electric development the terms would have to include the maintaining of the present power house as enlarged in accordance with the above information as a stand-by, and the fixed charges upon this power house would have to be considered in any new agreement or arrangement that is contemplated.

The amount of electrical energy consumed during the past year in Edmonton was 23,400,000 kw., and it is estimated that within two years the consumption will be 35,000,000 kw.

Further information may be obtained from the mayor of the City of Edmonton, Joseph A. Clarke.

BOOK REVIEWS

Corona Discharge, by Earle H. Warner and Jacob Kunz, the University of Illinois Equipment Station, Urbana, Illinois.

In view of the high voltages in use to-day and being considered for use in the transmission of power, the subject of corona loss becomes of much importance. This publication of the University summarizes and discusses the results of experiments which have been conducted at the University for some time past by the means of high tension direct current.

Schweitzer and Conrad, Inc., Chicago, have issued a folder relative to the electrical equipment necessary for providing the farm with electric power from transmission lines of moderate voltages. In particular the S and C type XW switching and protective combination is featured. This includes horn gap arrester, disconnecting switch choke coil and fuse mounting, grouped in one single unit and adapted for regular service on lines up to and including 25,000 volts.

C.A.S.E. WILL MEET IN WOODSTOCK

The annual convention of the Canadian Association of Stationary Engineers will be held in Woodstock on June 22, 23 and 24. The secretary-treasurer of the convention is John McCalley, 20 Riddell St., Woodstock, Ont.

The India Alkali Works, India Wharf, Boston, Mass., have issued a four-page folder descriptive of their soap powders, grit powders and cleaning powders.

Put a Farnsworth System to Work in Your Steam Plant

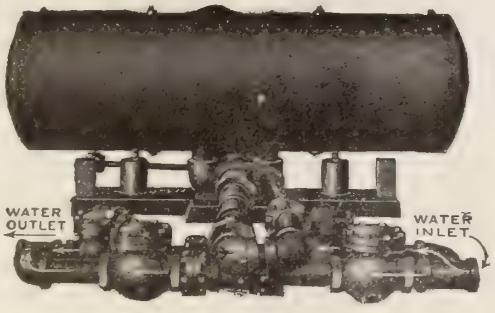
Farnsworth-equipped plants produce more steam with less fuel and less expense than other plants. Thousands of dollars are being saved by the Farnsworth System, not alone in Canada and United States, but in all countries of the world, wherever steam is used for heating or manufacturing process work—its value is thoroughly proven!

When the amount of expense saved by Farnsworth equipment is taken into consideration the question of installation costs is eliminated. It quickly pays for itself. It is a safe and profitable investment. Experience proves that in the majority of cases only three to six months' operation is required to return first costs.

These are facts. Plant owners have nothing to lose and everything to gain by investigating the Farnsworth System and the engineering staff of The Canadian Farnsworth Co. will be glad to advise and co-operate with them in solving steam line drainage and boiler feeding.

The Farnsworth Automatic Duplex Boiler Feeder

The "Farnsworth" should not be confused with ordinary steam traps. It is a machine built for Boiler Feeding. Note the cushioned dashpots, a feature which provides against shocks and ensures smooth operation.



The Sign of Coal Saving

No leaky steam valves with the Farnsworth in your plant; no constant waste of steam to the outside air; no springs to loose their tension; no levers to jump out of place; no weights to cause poundings, and no trunnions to bind and stick, or leak water and steam.

The Duplex feature of construction ensures a continuous flow of feed water to the boiler. Then, the machine being always equalized with the boiler provides against sudden shock or jar in the feed lines. There is no hold-up on the return lines as is the case with ordinary return traps, as the feeder is constantly receiving the water.

Our expert steam and condensation engineers are at your service. Have them investigate and make reports.

REGISTERED COPPUS U.S.PAT.OFFICE *In Paper Mills*

STEADY steam pressure is a vital factor in making good paper. A sudden drop at the gauge might mean serious loss in the mill. Keeping up steam is a matter of prime importance.

That is why modern paper mills are equipping their power plants with COPPUS Turbo Blowers to maintain constant steam pressure under varying conditions of load, fuel, and weather.

For instance, the COPPUS Blowers shown above operating in the plant of the Hampshire Paper Company, makers of good paper, at South Hadley Falls, Mass., have kept steady steam pressure with very satisfactory results. Peak loads are quickly met, steam pressure is always constant, and cheap fuel is economically burned.

COPPUS Turbo Blowers are helping out engineers and speeding up boilers in power plants the country over. Their good work is not confined to the paper industry—it extends wherever power is used and coal is burned. If they are not already working for you it is likely that they could save time, money and labor in YOUR boiler room.

ISSUED TWICE A MONTH

New Canadian Enterprise.—The Diamond State Fibre Co. of Canada has been incorporated to engage in the manufacture and sale of vulcanized fibre, known under the name of "Diamond Fibre." In the electrical field it is used for insulating bushings, gaskets, washers, wire conduits, etc., while in the mechanical field it is used for noiseless gears, discs, wheels, timer rings, etc. A mill will be built in Canada as soon as conditions warrant such a move. Mr. T. Elwood Webster is managing director of the company, and is located at 455 King St. W., Toronto.

An important improvement in the manufacture of coal gas has been perfected by the engineers of a gas company in London, Eng. They have contrived to extract from the gas all the carbon bisulphide—a substance which, when burned, had a deleterious effect on health and also on various materials. Throughout most of the nineteenth century, chemists and engineers strove to solve this problem, but success did not come till the year 1914. The war prevented the erection of plant to carry out the process, but the way is now open for the general adoption of a method which will make a gas flame as harmless to its surroundings as a candle.

TENDERS

The St. Thomas, Ont., Board of Water Commissioners offer for sale one Allis-Chalmers horizontal compound steam pump, two Worthington duplex pumps, one centrifugal pump direct-connected to engine, and one 7 h.p. vertical engine. Particulars can be obtained from the City Engineer, St. Thomas.

The City of Moosomin, Sask., will receive tenders up till May 5 for the supply, delivery and erection of internal combustion engines, generator, exciter, switchboard, street lighting apparatus, pole, wire and line material, power station and cooling chamber. Plans and specifications can be obtained from the Consulting Engineers, Saskatoon; Town Clerk's Office, Moosomin, Sask.

HELP WANTED.

DESIGNING ENGINEER—IF YOU ARE EQUIPped to take hold of an established line of Pressure Reducing Valves and push them to perfection, you have an opportunity before you. Answer clearly and fully on the following points.

(1) Have you basic knowledge of designing and actual experience? This is absolutely essential.

(2) Can you design special Valves such as Relief, Globe, Check-Reducing Valves for High Pressure. Any experience?

(3) As designer and Production Engineer, could you take active charge of mechanical end and maintain maximum production? Any experience?

(4) Give age, experience, full references, and salary expected. Strictly confidential. Will not write references without your consent.

The business is established, located in the Middle West. A good paying proposition with a bright future. Write immediately. Apply Box 1, A.P.H., Power House, 143 University Ave., Toronto.

Use The LONG STEAM for TRAP SATISFACTION

Automatically drains jacket kettles, separators, steam mains. Works against 1 to 200 pounds pressure. Has two outlets and is installed in any position. DOESN'T FREEZE.

The Hamilton Powder Works, Beloeil, P.Q., use them with great success. **Read this letter.**

Dear Sir: We have used one of your steam traps for a long time and have found the same to answer the purpose as well as any seen in operation. We were so pleased with the working of this steam trap last winter that we ordered six more this season and have fitted them up at various points in the works where live steam is used for heating purposes.

(Signed) J. Murray Wilson, Superintendent

Our trap will give you the same satisfaction as recorded above. Investigate and you'll be satisfied, too.

NON-CORROSIVE
CYLINDER OIL
MANUFACTURED ONLY BY
E. H. KELLOGG & CO.
NOS. 242 TO 244 SOUTH ST. NEW YORK U.S.A.
FRICTION LOSS

An overload is often a necessity. But it is hard on an engine. To successfully carry an overload so that there will be no after effects on the engine a very careful selection of your oil should be made. An oil that is not free from impurities will cause a greater wearing on the bearings, a great friction loss will occur. You will need to fire the boiler more often because the engine will be harder to run. In this manner you lose out. You work harder, have larger operating costs, and less power all because of your oil. Do as a great many Canadian engineers have done — give Kellogg's "Non-Corrosive Cylinder Oil" a trial. Absolutely pure. Write us regarding it.

E. H. KELLOGG & CO.,

MORSE CHAIN

In a Big Railroad Shop

Where Every Ounce of Power and Inch of Space Count

This Morse Chain is delivering power to an 80" boring mill from a 15 H.P. G-E Motor running at 1200 R.P.M. The chain is exposed to all the grit and dust of the shop. It is 4" wide and connects a 17 tooth pinion with a 120 tooth wheel directly below—a distance of only 33" between centers.

No record has been kept of the age of this particular Morse Drive but the boring mill is known to be one of the oldest in the shop and one of the first to be individually driven, so it is safe to state that this Morse Chain has been many years in service of the most unexacting nature.

Shouldn't you bear these facts in mind when you plan your next transmission drive?

THE JOSEPH G. BRANCH
SCHOOL OF ENGINEERNG :: CHICAGO

COMPLETE COURSE IN STATIONARY ENGINEERING

covering every branch of power-plant work, including Steam Engineering, Practical Mathematics and Electric Wiring. The Course has been prepared by a staff of experts working under the personal supervision of Joseph G. Branch, B. S., M. E., for many years Chief Engineer of the City of St. Louis and head of the Examining Board of Engineers for that City. Although complete in every detail, the Course is written so simply and clearly that anyone can understand it. No useless theory—but all the straight facts you need to pass the Engineer's Examinations and hold down a good job.

Special Offer—Mail Coupon Quick

The price of the course is extremely low and just now we are making a special limited offer to those who reply to this advertisement. This remarkable offer reduces the cost of the complete course to a very low figure. You will be astonished to find how little this tremendously valuable training will cost you. Mail coupon at once for full particulars and special monthly terms.

Save Your Plant
And 10 to 15% of Your Coal Bill

Two Causes of Disastrous Boiler Explosions

I. Cold water was fed to boiler, thereby weakening the structure.

II. The feed water contained a large amount of inorganic matter.

WHERE THE BOILER-HOUSE ONCE STOOD

The feed water contained a large amount of inorganic impurities and was fed cold to the boiler. It was the practice to blow some water out twice each twelve-hour shift.

From POWER April 1, 1919

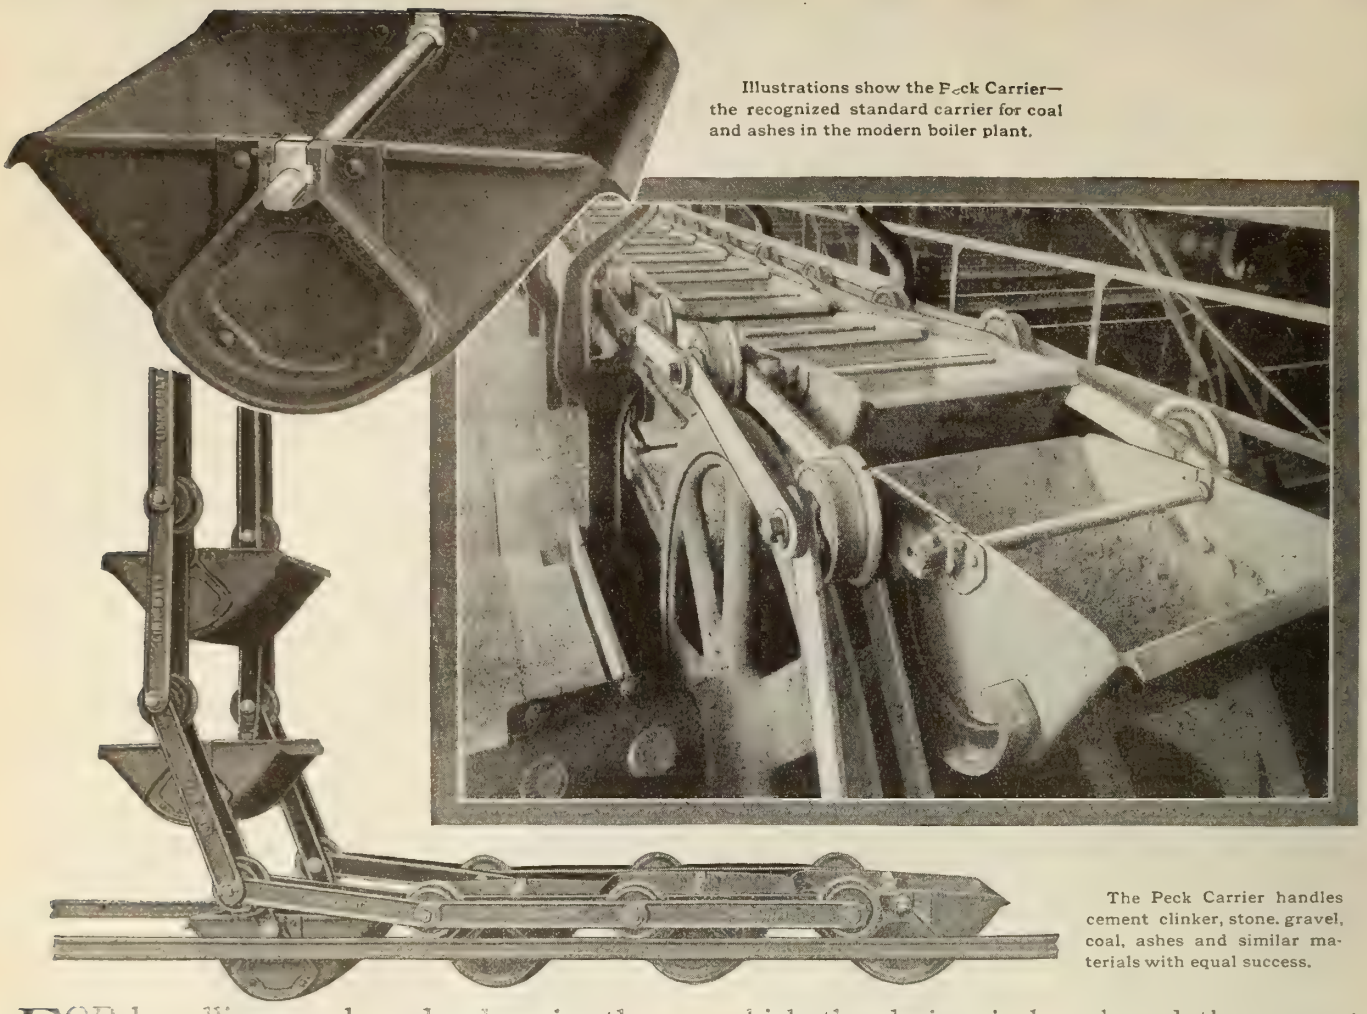
GREEN'S ECONOMISERS

I. Will heat your feed water from available heat in the flue gases which would otherwise be wasted, thus eliminating stresses which are set up when cold water is fed directly to the boilers, as wll as saving fuel and increasing boiler capacity.

II. With their slow circulation of water through the tubes, allow scale forming impurities to settle in the form of a sludge in the bottom headers, which can be blown down or washed out with a hose.

Our engineers will be glad to submit data showing the savings that have been made in other plants where economizers are installed, and will tell you what might be accomplished in your own plant.

GREEN'S ECONOMISER, LIMITED, TORONTO



Illustrations show the Peck Carrier—the recognized standard carrier for coal and ashes in the modern boiler plant.

The Peck Carrier handles cement clinker, stone, gravel, coal, ashes and similar materials with equal success.

FOR handling coal and ashes in the boiler house the Peck Carrier maintains a uniform record for low-cost per ton carried, and exceptionally low upkeep cost.

During the first three years of its operation, the Peck Carrier maintenance charges should be almost negligible.

This is due to the correct design of the entire machine, the correct principle upon which the design is based, and the rugged, sturdy construction of all parts entering into it.

Back of the Peck Carrier stands the reputation of this Company—and hundreds of successful installations. Read our Peck Carrier Book No. 220. Address nearest office for copy.

GARLOCK
Nine Fifty Gaskets

Are unsurpassed for superheat steam joints and are equally well adapted to air, acids, ammonia, or any condition where gaskets are required.

The material from which these gaskets are cut is made of the highest quality of asbestos, built up into sheet form under tremendous pressure, thus securing great toughness, flexibility and tensile strength.

Nine Fifty gaskets do not require following up after having been applied, and joints can be opened as often as desired without injuring the gaskets.

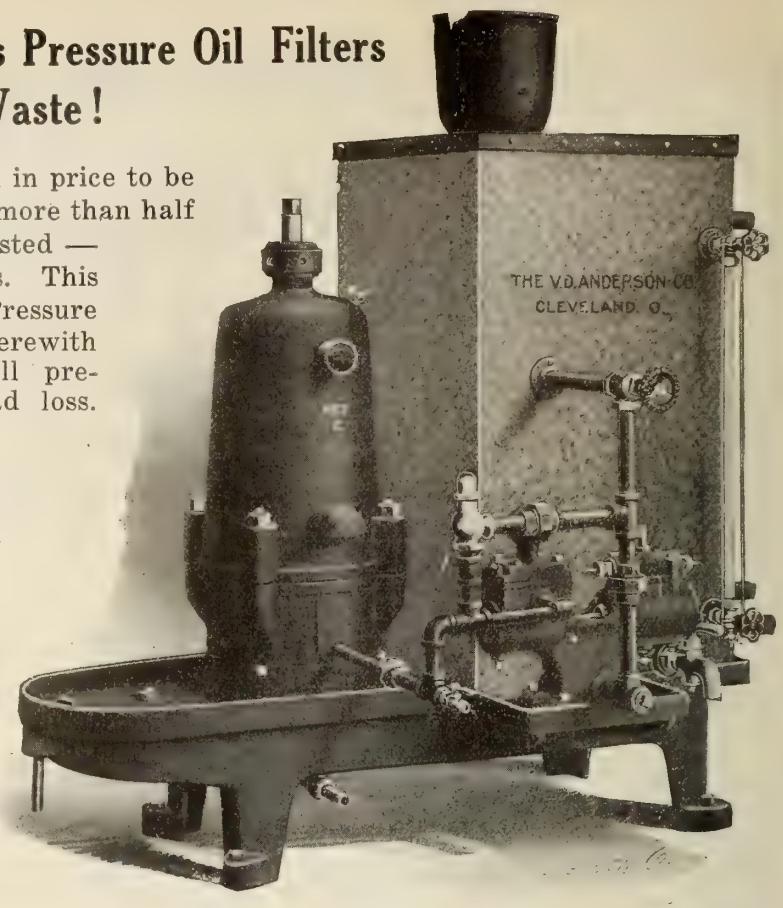
Why Waste Oil?

Anderson's Pressure Oil Filters Prevent Waste!

Oil is too high in price to be wasted. Yet more than half your oil is wasted — lost on wipers. This Anderson Pressure Oil Filter herewith illustrated will prevent this dead loss.



Place drip pans beneath engines and machinery. Then pass this oil through the **Anderson Filter** and you will have oil just as clean and as pure as the new oil you purchase.

You can use oil over and over again with the **Anderson Filter.** No other filter will do the work so thoroughly.

There are a few more points about the Anderson that we would like to take up with you. Pleased to have you drop us a line.

LINCOLN ARC WELDER

Don't Let a Defective Boiler Shut Down Your Plant

Of all the untoward occurrences that happen in every plant, the most serious is the defective, leaky boiler.

In most plants this means a "shut down" —usually for some days.

Every efficient organization will be interested in knowing that we can make the most complete boiler repair, in a few hours—that, by any other method would take days.

We maintain special equipment for hurried calls, which we can bring at once to your door.

In the list opposite are the classes of plants that are today employing the Lincoln Arc Welding Process because it means a distinct saving of time to them —and time is money.

It will not obligate you in any way to get in touch with us. Phone Main 3768 if convenient, or write or wire for complete particulars.

Do this now — you will be surprised at the wide variety of work that is done with Lincoln Electric Welding.

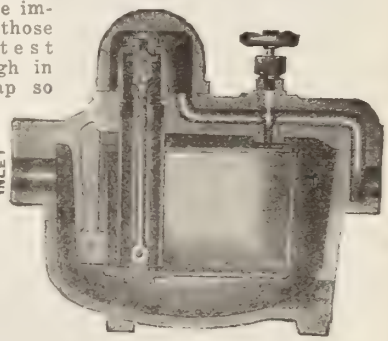
KIELEY

IMPROVED HIGH AND LOW PRESSURE

STEAM TRAP

For General Service

No power plant should be without a dependable steam trap. It is the great economizer of fuel and promoter of power plant efficiency. The KIELEY Improved Trap is the latest development in the art of steam trap construction, and is suitable for all service, either high or low pressure. The important parts and those subjected to greatest wear are placed high in the top of the trap so that by removing two nuts and the small cap all parts are easily accessible and removed for repairs — no breaking of connections necessary, neither do you have to remove the cover. Seats and discs are of best metal, absolutely non-corrosive; for exceptionally severe service seats and discs are constructed of nickel or monel metal, and the bodies of cast iron. Kieley traps never leak when in service—our water seal assures you this.



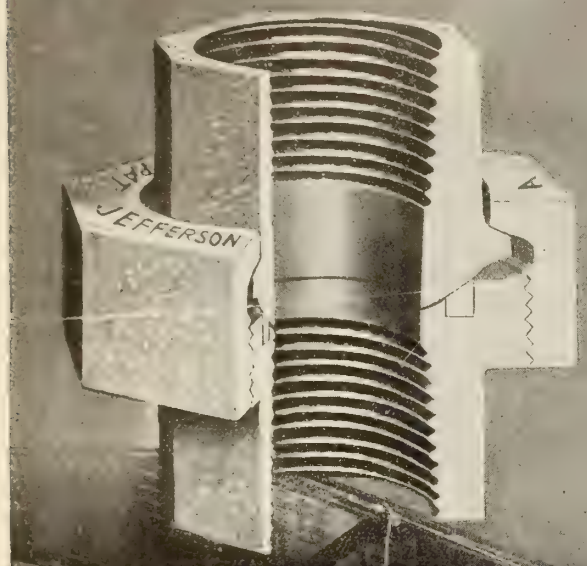
Leaky, unreliable steam traps are expensive. Adopt the KIELEY and be certain of efficient, economical service.

THE ARTHUR S. LEITCH CO.

Kent Building, TORONTO

JEFFERSON

"Look for the Name on the Nut"



Insurance Against Breakdowns!

To make long, heavy pulls without faltering the **power behind the HOIST** must be absolutely certain. The steam pressure in the great cylinders must be constant and steady.

Jefferson Unions play a mighty important part in the steady and safe operations of HOISTS and other machinery.

Once you put a JEFFERSON UNION on the line, you can say "Good-bye forever" to union troubles because a Jefferson gives perfect service just as long as the line holds out.

Your jobber will supply JEFFERSON UNIONS. Talk them over with him—ask him to explain the difference between a JEFFERSON and one of the "just-as-good" variety.

Write TO-DAY for our Catalogue "UNIONS" which shows the complete JEFFERSON line.

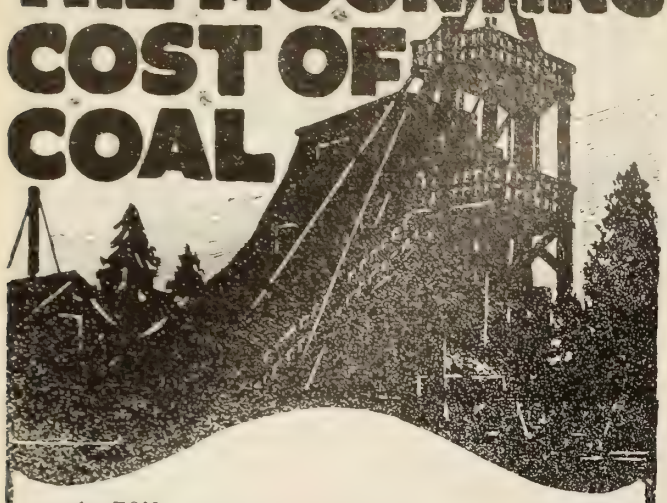
THE MOUNTING COST OF COAL



A TON of bituminous coal costs to-day nearly 250% more than in 1914. Of course, you can't get 2½ times as much heat out of that ton as you did six years ago—but you can get at least as much. Do your boiler room records enable you to check up on your heat per ton? Are you satisfied that every pound of fuel is being utilized to the best possible advantage?

There is no surer or more positive way of ascertaining than by installing a

YARWAY-LEA V-Notch METER

for it measures **accurately** the amount of water evaporated by the boiler, and records the figures in a permanent, easily-referred-to form. You can run your power-plant under a continuous, self-recording test, with every fluctuation in steam output shown as it occurs. With a complete record of performance it requires but a moment to discover whether or not that costly fuel is autually doing its duty.

We shall be glad to explain more fully the advantages of the Yarway-Lea V-Notch Meter, if you are interested, and to give you the names of some of the prominent users who have signified their satisfaction by reorders.

Shall we send Bulletin L40? It contains some interesting information on boiler room records.

WORKS WELLAND ONT.

In cold dollars and cents

—how much is 25% of your coal bill?

We are specialists in combustion engineering. We manufacture other boiler instruments besides the recorder illustrated, and we are ready at all times to answer your enquiries on any phase of the subject.

Is it worth saving, or would you prefer to keep on throwing it away?

Don't think we're making a rash statement. **Innumerable results have shown that 25% of all the fuel burned under steam boilers is wasted by preventable heat losses in the boiler furnace alone.** These losses **cannot** be prevented by "efficient," up-to-date equipment. **"Efficient" equipment is only as economical as its operation allows it to be,** and it's operation we're talking about. Even the most modern and up-to-date power plant will waste 25% of its coal bill, just as we say you are doing, unless proper steps have been taken to prevent the waste.

To save that 25%, you need accurate information of the furnace conditions at all times. Then you need the knowledge to apply this information to prevent the losses.

The Hays Automatic CO_2 and Draft Recorder obtains an accurate and continuous record of the two essential furnace conditions. Our book, "How to Build Up Furnace Efficiency" helps you to interpret these readings, to locate and measure the losses. It shows you how to stop these losses once they are located, and how to keep them stopped.

We suggest that you send for this book. It's good enough for your library, it's interesting and entertaining — in no sense a catalogue— and it's gone through 14 editions.

If It's Rubber We Make It

Rubber has become probably the most universally used material in the world. In every factory, office, store, and household, some article of rubber is used daily as an important part of the equipment. Few users recognize its utility or its quality—to them the important item is price.

When you buy rubber goods be certain that you get a Dominion Rubber System product. It is your assurance of superior quality and satisfactory service. These products include Rubber Goods for every conceivable purpose in standard stock sizes, or specially made to meet your needs, in factory, mill, mine, lumber camp, shipbuilding, marine, or other industry.

Dominion Rubber System Products

BELTING—For power transmission, conveyor, and elevator service. Bucket belts, Vanner belts, belts for brick-making machinery, lumbering, and all exposed or outside work.

HOSE—For steam, air, water, oil, acids, suction and sand—fittings and nozzles.

PACKINGS—Sheet packings and special packings for high and low pressure service, and for every other purpose.

MOULDED RUBBER—Plumbers' supplies, matting, tiling, special moulded and cut goods.

FIRE EQUIPMENT—Hose, coats, covers, reels, brass fittings, helmets, etc. Also a complete line of fire-fighting necessities for factory and home.

Our technical experts will gladly assist you, without cost, to select such equipment as you may require for regular or special service.

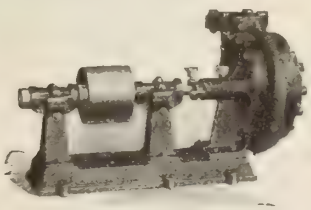
AMERICAN-MARSH PUMPS

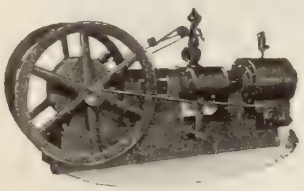
SIMPLE **RELIABLE** **EFFICIENT**

The American-Marsh steam pump is an improved form of the famous Marsh Pump which has been on the market for over thirty years, during which time over 150,000 have been manufactured and sold.

The American-Marsh Pump has no internal stuffing boxes, no tappets and no slide valves. The auxiliary valve is of the semi-rotative disc type of an improved design. The main steam valve is of the balanced piston pattern, assuring highest efficiency. The water ends have large valve areas and are fully bronze fitted, including solid bronze piston rods and bronze removable water cylinder bushings.



American-Marsh Centrifugal Pumps are made with the same high grade of material and workmanship which characterizes the construction of the steam pumps. They are made in all sizes up to 12 inch, both single and two stage for heads up to 250 feet.



The line also includes—

Power Pumps
Deep Well Engines
Air Compressors
Jet Condensers
Dry Vacuum Pumps
Boiler Feed Pumps

A Goodyear Belting man will survey your plant with no obligation to you.

GOODYEAR

MADE IN CANADA

Where Belts Meet Dampness!

Goodyear Extra Power Belt Delivers Power and Lasts

Damp or wet belts usually slip more easily than dry belts.

Water and moisture form a thin film between pulley and belt.

Here "Extra Power" Belting especially displays its advantages.

Where there is water, moisture or steam — around the beaters in paper mills, for instance—Goodyear Extra Power delivers the power load just as under more favorable conditions.

Because Goodyear Belting has a rough friction surface which bites through the film of water and clings to the pulley, costly slipping is overcome.

Moisture rots belts, if it gets into them.

Goodyear Extra Power is rubber-sealed against moisture.

Not just enclosed in a rubber envelope.

The high-grade rubber in Extra Power is forced through and through the fabric, surrounding and protecting every strand, making the belt practically a solid unit.

That Goodyear Extra Power Belting is just as efficient and just as economical in damp or wet places as in other transmission uses, is proved by these satisfied users:

> The Provincial Paper Mills of Thorold got 16 months' service from Goodyear Extra Power on a Jordan Pump where they had been getting about one month's service. They also say — "In the room where our beaters are located, the air is constantly damp. Here we have found Extra Power so superior that we use it exclusively."

Some other firms who will be glad to tell you of the satisfactory service of Goodyear Extra Power under damp conditions are:

Mittagami Pulp and Paper Co., Smooth Rock Falls, Ont.
Port Arthur Pulp and Paper Co., Port Arthur, Ont.
North-West Laundry Co., Winnipeg, Man.
Dominion Pulp Co., Chatham, N. B.
Bathurst Lumber Co., Bathurst, N. B.
Gloucester Lumbering and Trading Co., Bathurst, N. B.

If you use belting, it will pay you to hear about the Goodyear way of supplying it. It will cost you nothing to have a Goodyear man call and show you how to overcome your problems. Phone, wire or write the nearest branch.

PUTS AIR TO WORK

THE NEW A-7 TURBINE-TRANSMISSION

A BRAND-NEW DRIVE FOR STOKERS—FANS—PUMPS

The cumulative experience of 60 years is expressed in the design and construction of this new unit. The unique features allow highest turbine efficiency while the stokers, fans and pumps are working at their most economical speeds.

The turbine is supported directly from the transmission casing—flexible couplings are eliminated—no sub-base is necessary—alignment trouble is impossible—and lubrication is automatic.

Much time has been spent in carefully designing this unit. Thorough tests were made in our shops long before anyone outside of our organization was asked to prove its merits under actual working conditions. For over a year a number have been in use, by several of our customers, with remarkable satisfaction.

It is with confidence and readiness that we ask you to acquaint yourself with the possibilities of this practically tested driver. You will find our Turbine Department always prepared to co-operate with you.

Write for Complete Information.

Make this Book Your Buying Guide

It will keep you in touch with every phase of mechanical equipment, no matter what your business may be. It will keep before you the advantages of concentrating your buying in one place, where everything mechanical needed for the factory, power house, machine shop, garage or farm is obtainable.

It should be permanently on the desk of every purchasing agent—every buyer of mechanical goods. Write to-day for your copy of

General Catalogue No. 20

the most complete compilation of information for the Canadian buyer of mechanical goods, departmentalized, conveniently thumb-indexed, and cloth-bound.

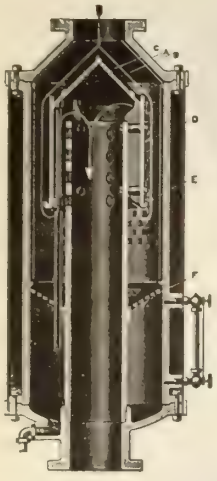
III IMPORTANT THINGS
TO CONSIDER ABOUT
A SEPARATOR



I. THE PLAN—Is it sensible, will it work, no matter how large the Separator or how well made?

II. THE SIZE—Is it big enough regardless of plan, will it hold a good dose of water?

III. THE CONSTRUCTION—Is it strong enough, are flanges heavy, how will it look by the side of a nicely finished engine? Send for catalog and note these points in

Sweet's Separators

TRADE MARK REGISTERED

STRENGTH—GOODNESS—QUALITY

Performance Facts of Durabla Gasket Material

Tight joints are made and maintained by DURABLA under the following severe services and conditions:

Steam:	275-300 lbs. pressure; 275°-300° superheat.
Oil:	Pressure still joint re-made over 160 times.
Gasoline:	Cylinder heads of gasoline engines and pumps.
Acids:	All acids that can be carried in pipe lines.
Water:	Equally satisfactory with temperature of 40° or 210° F., at any pressure.
Ammonia:	Both absorption and compression systems of refrigeration.
Air:	Air lines and cylinder heads of compressors—all types.

One Standard material for all gasket work—Sold on a Service Basis

DURABLA is sold in sheet or gasket form and the trade mark is stamped all over the material.

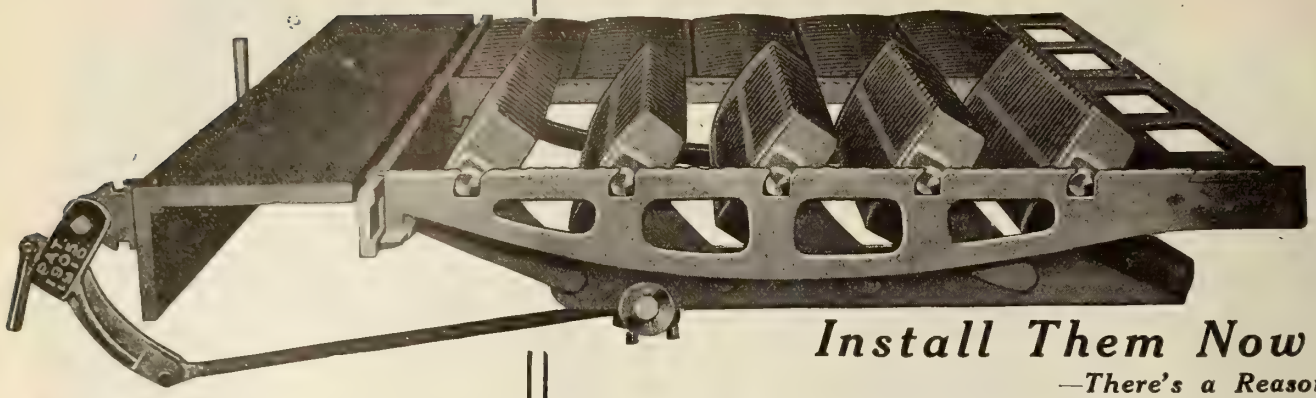
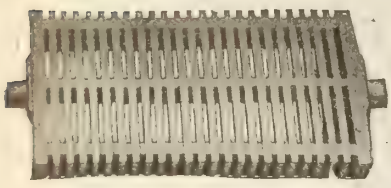
The real expense of packing a valve is the labor.

The amount of packing used is small.

It's economy to use the packing of long service.



Cyclone Grates



Install Them Now!

—There's a Reason

Think of the price you are paying for coal! Think of the price you will pay when fuel takes another jump. Then think of this — Cyclone Grates will save you at least 10% of your fuel costs, because they provide for 60% air space and 90% underdraft, which enables you to burn every bit of fuel that goes into the furnace, and at the same time enables you to burn the cheapest grades of coal and secure maximum results. Cyclone Grates help you to meet the high cost of fuel — install them now and save expense!

SPECIAL NOTICE—We are prepared to install Cyclone Grates on genuine 30-day trial basis. Details gladly furnished.

METLSKIN

prevents boiler-scale

by a process which is mechanical, rather than chemical. It forms a minute, grayish-white coating which keeps scale-forming solids from adhering to the boiler metal, and, therefore, these solids must settle to the mud-drum, whence they may be discharged through the blow-off.

METLSKIN is distinctly **not a compound,** nor does it contain any soda ash, graphite, kerosene, or tannin. It works by expansion, without harm to anything save boiler-scale itself.

The Two Months' Test

may be adopted by any reputable concern troubled with scale. METLSKIN will remove the old incrustation safely, but gradually, will ultimately produce clean boilers and then **keep them clean.**

Send a post card for terms and full details.

NOPORO

air-proofs boiler-settings

by maintaining an air-tight seal on the exterior surfaces of the brickwork. After a thorough application, by means of a trowel, NOPORO forms a covering that looks and feels very much like coarse, black grain leather. The surface may be whitewashed after an interval of 6 to 8 days, while the material below the surface retains its plasticity. It will not peel, check, or disintegrate, and will stay put for years. No further attention need be given it.

An Immediate Saving

may be effected, since NOPORO promptly prevents the entrance of cold-air into the furnace chamber. That means better fuel-combustion, less firing, less coal. NOPORO pays for itself from the first.

Mail a card for prices and descriptive folder.

HOMESTEAD
Quarter-Turn Valves

There's a Homestead for every purpose

Whenever you are in need of tight, efficient, positive-acting valves—order "Homesteads."

They are all constructed with the patented "Homestead" principle which locks the valve tightly to seat when the valve is closed, and which limits the operation of the valve to a quarter turn of a convenient handle.

Only one quarter of a turn is required to open or close these high-grade valves. Adopt them. You'll save time, trouble, and expense. Our catalogue contains some interesting information.

Homestead Valves are made in Straightway, Threeway and Fourway patterns.

ENGINEERING EQUIPMENT

DON'T THROW AWAY YOUR VALVES

Like many other concerns, you probably have been in the habit of throwing away your old valves. This, of course, is a necessary practice with valves of the ordinary type. As soon as the seating is too far gone for service they become worthless.

With an equipment of Pratt & Cady Renewable Seat Gate Valves, it no longer becomes necessary to consign a valve to the scrap heap when the seat is worn out.

Renewable seat rings — to take the place of the old ones — give the valve a new lease of life, and a long lease, at that. All parts, being of the best grade of pure metal, possess tremendous endurance and give the utmost service. This combination insures an unusually long life.

In the course of a year more valves go out of commission in the average plant than you realize. Add up their cost, large and small, and you will be surprised at the total. Pratt & Cady Renewable Type Valves will save you the greater part of that total!

Ask us for the names of satisfied users.

Booklet on request. Write for it to-day.

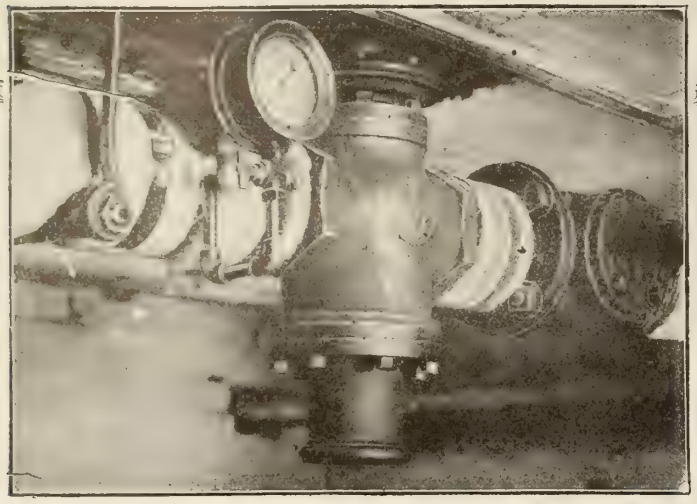
MASON

POWER HOUSE SPECIALTIES



Stand the Test of Time

No better proof of the quality embodied in **Mason** Specialties is needed than this: in 1896 the **Mason** Standard Reducing Valve shown in the illustration was installed in the Protestant Hospital for Insane, at Verdun, Montreal. It was repaired for the first time in September, 1919, and is giving as efficient service now as the day it was installed.

Mason Standard Bronze Reducing Valve.

Three Valuable Factors

To Be Considered in Choosing Equipment

Choosing the finest material for the purpose and employing the best of skilled hands in making and assembling the parts assures a standard of excellence in **quality** in all **Mason** specialties. This quality means long, dependable service. Last but not least, our salesmen are practical engineers. They are trained to give valuable service to prospective buyers; they advise the best equipment for the purpose — from experience, not catalogue!

DEPARTMENT OF LABOUR

Ontario Government

Minister: Hon. W. R. Rollo **Deputy Minister: W. A. Riddell, Ph.D.**

NOTICE TO STATIONARY AND HOISTING ENGINEERS AND STEAM PLANT OWNERS

Everyone operating a **Stationary** steam plant of 50 B.H.P. or over, and everyone operating a **Hoisting** steam plant working at a pressure of 20 pounds or over, irrespective of horsepower and used for hoisting in structural operations or excavating purposes, in the Province of Ontario, must hold a certificate from the Board of Stationary and Hoisting Engineers. Application forms will be forwarded upon request.

After January 1, 1920, all stationary steam plants in the Province of Ontario must be registered with the Board of Stationary and Hoisting Engineers. Application forms will be forwarded upon request.

All applications should be mailed to the Chairman of the Board. W. C. McGhie, Department of Labour, 15 Queen's Park, Toronto.

NOTICE TO MANUFACTURERS, DEALERS AND USERS OF STEAM BOILERS

All steam boilers built in, or entering, the Province of Ontario, and boilers exchanged or repaired, are subject to Government Inspection as prescribed in the Steam Boilers' Act, 3 George V., ch. 61.

Before any work of repair or alteration is commenced on any boiler, notice must be sent to the Department stating the nature and extent of the repairs or alterations proposed to be made. If the Chief Inspector should consider such repairs or alterations of an extensive character, the boiler must be inspected in accordance with the Regulations by an Inspector authorized under the Act.

All communications should be addressed to the Steam Boiler Branch, Department of Labour, 15 Queen's Park, Toronto. D. M. Medcalf, Chief Inspector of Steam Boilers.

A HELPING HAND

Engineers, firemen and other power plant operators are earnestly requested to take up any matters upon which they desire information with the Editors of POWER HOUSE. This applies particularly, at the present time, to the grading of certificates in Ontario. Any new development of this kind naturally gives rise to a period of uncertainty and information is often desired by those who are most intimately concerned. We are in a very advantageous position for extending a helping hand to those in doubt as to what to do under the new regulations. Questions regarding the Act, its regulations and their interpretation, requirements for the different grades, studies to be undertaken, etc., will be cheerfully answered.

Handling Costs Reduced

from $65 Daily to One Man's Wages by Installing Jeffrey Coal Conveying Equipment

Showing interior view of head end of 20-in. Belt Conveyer over bunkers operated over a self-propelling belt tripper.

The new generating plant of the Mansfield Electric Light & Power Company, located at Melco, Ohio, 13 miles southeast of Mansfield, offers a striking example of the economies that can be effected by the substitution of modern equipment for old-time methods. All equipment used is the last word in efficiency.

The coal for this plant is unloaded from railroad cars into a steel hopper, or dumped into a submerged storage into a 2000-ton concrete bin, which now stands where the coal pile is shown in top illustration.

From track hopper, a 30-in. Reciprocating Plate Feeder regulates the flow of coal to a Jeffrey 30-in. x 30-in. Single Roll Crusher, as shown in lower illustration, and a Jeffrey 20-in. Belt Conveyer carries the crushed coal to boiler house and distributes to bunkers.

The Conveyer proper consists of 736 ft. of 20-in., five-ply rubber belting. It is driven at a speed of 258 feet per minute and is supported by 80 standard 20-in., three-pulley troughing idlers, 36-20-in. return idlers and sufficient guide idlers.

The Jeffrey Equipment has a rated capacity of 50 tons of coal per hour, although the engineers in charge of this installation state that it is many times called upon to handle up to 70 tons per hour.

20-in. Belt Conveyer in the inclined portion from Crusher to boiler house.

Showing Reciprocating Plate Feeder under Track Hopper and 30-in. x 30-in. Single Roll Crusher which discharges the coal on foot end of belt conveyer.

Write for Jeffrey Catalog No. 175-4, featuring this and numerous other Belt Conveyer installations.

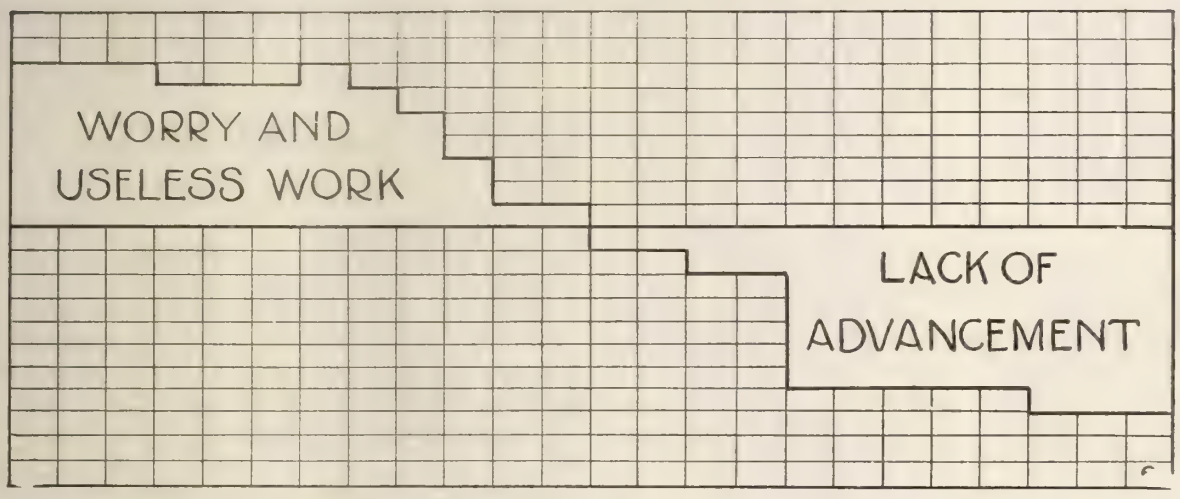
Let the *C.A.S.E.* Smooth Out Your Load Curve



Remove The Peaks of Worry And Unproductive Labor And Build Up The Valleys By Working For Your Advancement

A man who is thoroughly grounded in the practice of his profession, who is free from personal worry and trouble, overcomes the many difficulties besetting the path of the operating engineer with little labor and in a manner ensuring his advancement.

The successful man owes his success to a wise appreciation of the advantages and mutual help offered by association with those in the same field of endeavor. To join an association having for its objectives the welfare of the engineer in things mental and material, his advancement in knowledge and skill, his protection by provision for sickness and distress is to take advantage of an opportunity indispensable to all who hope to better themselves.

If you are interested in such an organization and live where less than fifteen engineers are located, send for a copy of our constitution and application blanks for admission to nearest branch lodge. If there are more than fifteen engineers in your community, get together and send for particulars regarding formation of a branch lodge.

J. H. HALE, General Secretary,

Three reasons why *you should install* BADGER SELF-EQUALIZING EXPANSION JOINTS

They will prevent leakage. They will not allow looseness. They will insure you against fractures in all pipe lines.

When Buying Thermometers
There's Just Three Things to Remember—

First, you must have accuracy and sensitiveness—

Second, durability is absolutely essential—

Third, the thermometer must be suitably constructed for the intended application.

Accuracy, sensitiveness and durability are absolutely guaranteed in

"Crescent" Thermometers

And with nearly seventy years of experience to our credit, we are qualified to properly interpret your needs.
Our Catalog P.H. 200 illustrates and describes "Crescent" Thermometers for every application. Also test thermometers, glass thermometers, etc.

Get a copy of Catalog P.H. 200 to-day.

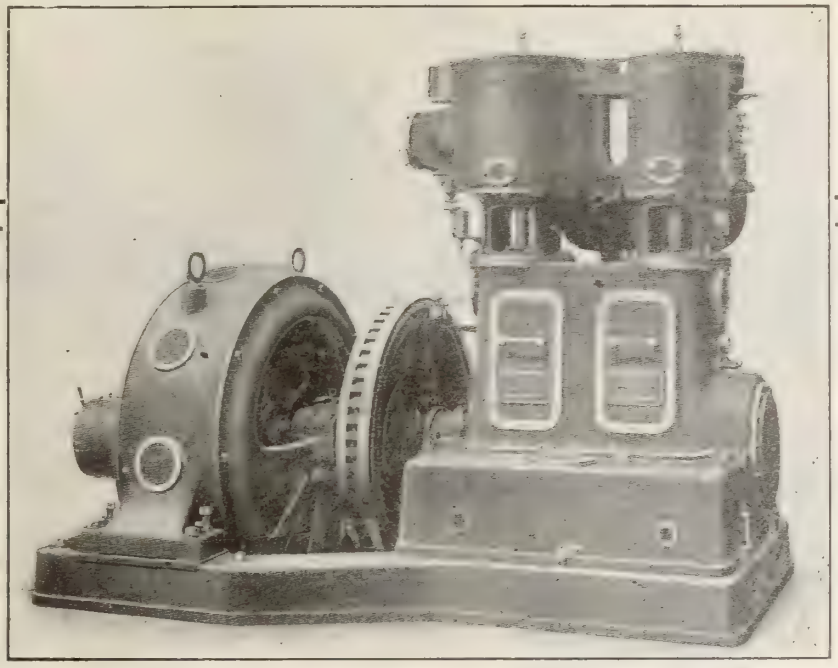
BELLISS & MORCOM
LIMITED

ENGINES AND AIR COMPRESSORS



Belliss & Morcom Motor-Driven Air Compressor.

HIGH-GRADE POWER EQUIPMENT

We are prepared to supply and install Steam, Gas, Diesel Oil Engines, Steam and Exhaust Turbines—on short notice. We have Engine Generator Sets ready to ship.

Send Us Your Enquiries For

Steam Engines	Condensing Plants	Hydraulic Pumps
Gas Engines	Centrifugal Pumps	Hydraulic Accumulators
Oil Engines	Boiler Feed Pumps	Pressure Filters
Diesel Engines	Water Wheels	Gravity Filters
Steam Turbines	Water Meters	Water Softening Plants
Air Compressors	Hydraulic Presses	Refuse Destructors

Activated Sludge Sewage Disposal Plants

We specialize in power plant design and erection. Put your problems up to our engineers, their services are at your disposal without obligation.

LAURIE & LAMB

ENGINEERS

211 Board of Trade Building, MONTREAL

We handle only quality equipment. It is selected and approved by our engineers and backed by years of service. When you are in the market you will do well to investigate our lines.

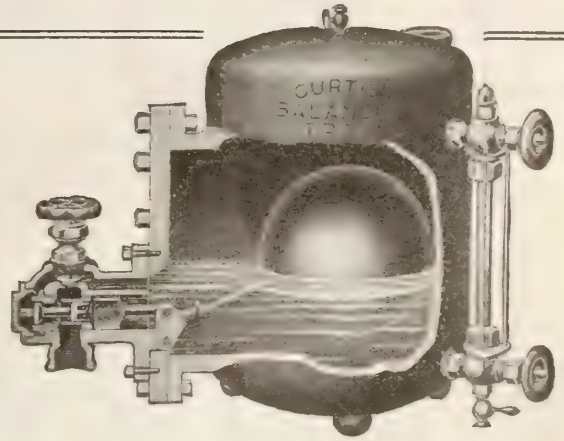
CURTIS Engineering Specialties



Five Superior Features of the Curtis Trap

1. A perfectly balanced valve.
2. An absolutely frictionless valve.
3. The valve can be removed without breaking a joint, starting a gasket, or taking out a bolt.
4. The valve being frictionless and balanced, the whole power of the float is available for opening and closing the valve.
5. Each trap will operate perfectly on pressure varying from one to 250 lbs.

KERR

("New KEYSTONE" Pattern) GATE VALVES

If you have not used any of these New Pattern Valves, specify "KERR" in your next order. We want you to get acquainted with the most reliable valve on the market.

If you have been using them, we are confident that our satisfaction will bring us your repeat orders. These valves will never cause you or your customer the slightest trouble. Their high quality is consistent.

When you buy a "KERR" Valve you get a guaranteed article that is backed by a reliable firm. Many of the largest distributers of valves in Canada have sold "KERR" Valves for over 25 years, and are still recommending them as the "Best Valve." Write us for particulars.

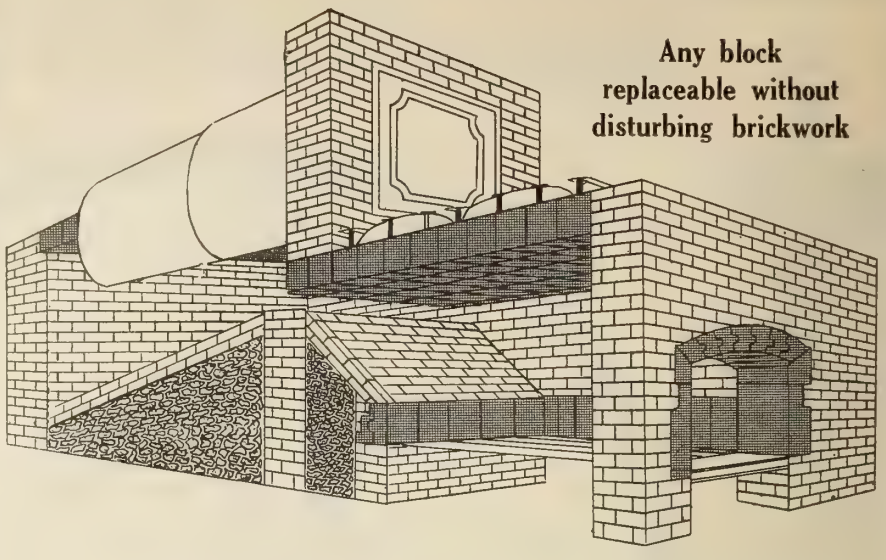
Permanent Satisfaction

Costly air leaks and rapid formation of clinkers materially increase the cost of making steam.

Gates Patent Furnace Linings

Close fitting, tongued and grooved joints prevent air leaks. Then the lack of projections eliminate the possible formation of clinkers. The material used is very hard and refractory; the softening point is 1700° centigrade.



Any block replaceable without disturbing brickwork

We specialize in all kinds of power plant brickwork. Our engineers are at your service. Call on them at any time for information—without obligation.

Reduce Your Overhead

THE proper use of selected lubricants is a sure means of reducing overhead expenses and of eliminating unnecessary operating costs. *Perfectly-lubricated machinery gets less wear and lasts longer.* Repair bills are smaller and fewer; depreciation is kept at the lowest possible figure when lubricants are chosen with an eye to mechanical needs and service conditions.

Imperial Lubricants are designed to meet definite needs and conditions. Made from the best crudes they are formulated and designed for real service. They are Canadian-made and readily obtainable everywhere in Canada through our extensive distribution system.

There is a "just right" grade of lubricant for each type of machinery and for each moving part—railroad, marine, power plant, factory and mill. The right use of Imperial Lubricants will reduce your overhead.

Imperial Lubrication Engineers are at your service for consultation. Their co-operation and recommendation for better lubrication are part of Imperial Oil Service.

Write us at 56 Church Street, Toronto, or at any of our branches, for an appointment or for further information.

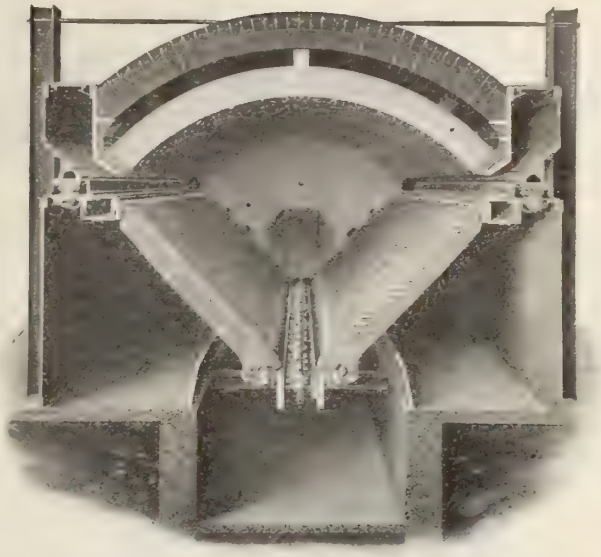
MURPHY AUTOMATIC FURNACES



For Any Boiler
50 h.p. and Up

Any boiler from 50 h.p. and up, can be equipped with the MURPHY FURNACE, The ***smaller plant*** can therefore enjoy all the economical advantages of fuel and labor savings ***without resorting*** to forced draft.

To-day over ***6000 boilers*** are fired by MURPHY FURNACES. You will find them used in nearly every branch of the industry from hospital to industrial and central station service. MURPHY FURNACES "burn any fuel that has heat in it." They double the output of the plant "without one penny for draft."

Our Catalogue "HM-4" shows how MURPHY FURNACES can be installed under any type of boiler—50 h.p. and up.

For information on RILEY UNDER-FEED STOKERS for large boilers see June 5th advertisement or send for RILEY STOKER Catalogue "HR-4."

MURPHY IRON WORKS

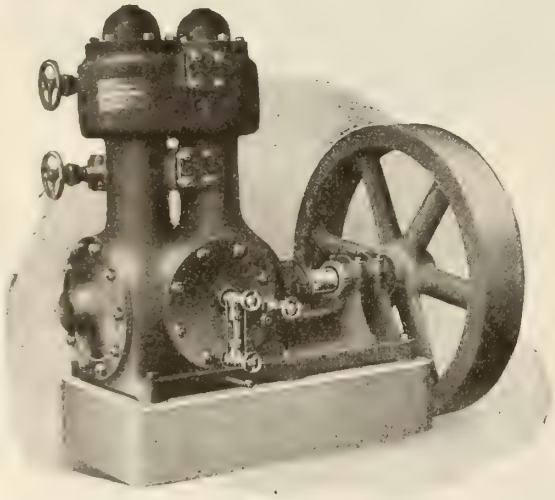
Mechanical Refrigeration



Reliable--Beneficial

THE many benefits common to all users of MECHANICAL REFRIGERATION, should make it a valuable adjunct to your business.

The uniform temperatures it provides have a better holding effect on the product in storage than ice, because the temperature produced by ice is not uniform, varying with the amount of ice in the refrigerator.

MECHANICAL REFRIGERATION permits the maintenance at all times of any temperature desired in the refrigerators or cold storage rooms, whereas you can not always get ice just when you need it, and a delay of a few hours often means a loss through deterioration of the product in storage.

If interested in MECHANICAL REFRIGERATION, a request for information and prices will receive our prompt attention.

Special Thermometers for Ice and Refrigeration

The Ice and Refrigeration Industry calls for thermometers especially fitted to many different needs, and accurate beyond doubt in every application.

TAG Thermometers are backed by 150 years of experience in making thermometers, and a close study of refrigeration and ice manufacture since the beginning of the industry.

On brine tanks, on ammonia lines, on condensers, in any connection, TAG Thermometers give the exact facts, facts that are essential to intelligent and economical plant operation.

Bulletin PP-370 illustrates many forms of Ice and Refrigeration Thermometers.

The following guarantee covers all TAG Thermometers.

Accuracy — Absolute and Constant.

Construction — Highest Grade Workmanship.

Material—Most Durable for the Particular Application.

Insurance — Against Loss by Breakage in Transit.

The insurance clause means that we shall assume the burden of obtaining redress from the Transportation Company, if the customer will notify us of damage immediately upon receipt of goods, and co-operate with us in securing the necessary evidence.

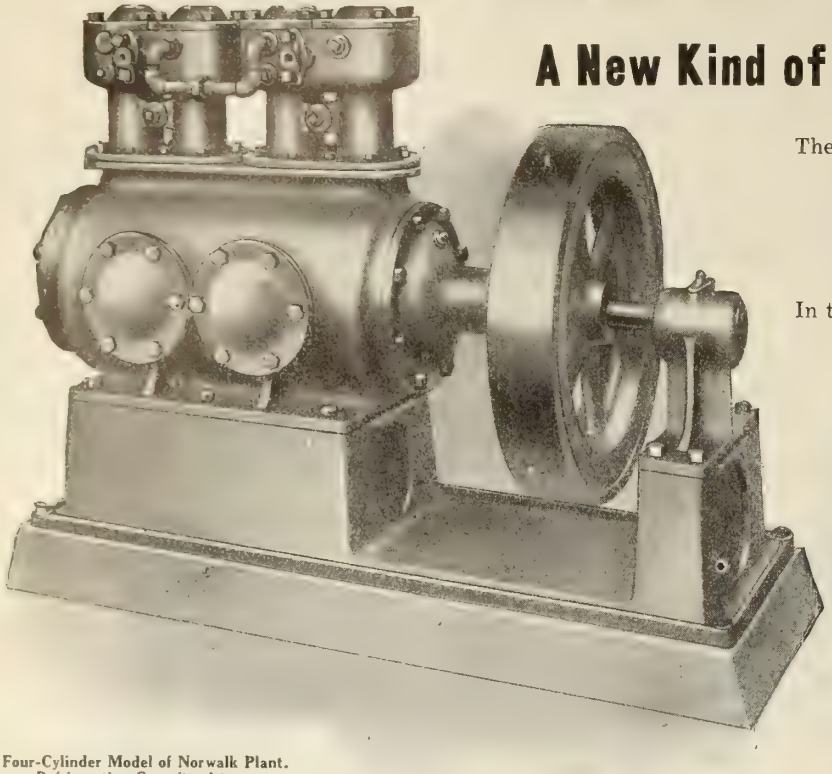
NORWALK
REFRIGERATING PLANT



Four-Cylinder Model of Norwalk Plant.
Refrigerating Capacity, 4 tons.

A New Kind of Refrigerating Service

The Norwalk Refrigerating Plant, now ready for the market, has been perfected to meet a wide demand for increased simplicity, reliability, economy and flexibility of service. Supplied in capacities from one-quarter ton up.

In the Norwalk the Compressors are greatly simplified in construction, and the multi-cylinder design permits of high speed and smaller-sized units. The machine is ruggedly built throughout. Can be direct-connected to a gasoline engine or chain-driven from a motor. All features have demonstrated their value in severe tests.

We provide attachments to adapt the Norwalk to any form of refrigerating or ice-making service. Write for details.

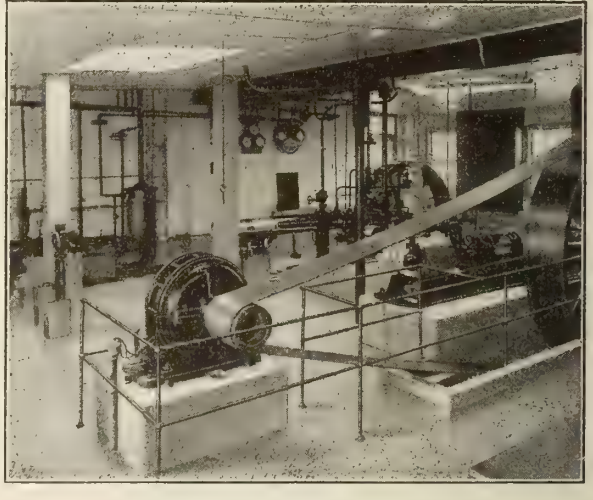
LINDE
Ice Making Machinery
Used by Large Firms

Many of the most prominent firms, corporations and institutions in Canada use Linde Refrigerating Machinery. Some of them include:

The Manitoba Cold Storage Co., Limited, Winnipeg; City Dairy Company, Ltd., Toronto; Civic Abattoir, Toronto; Wm. Davies Co., Toronto; Dominion Fish and Fruit Co., Quebec; General Hospital, Montreal.

These and many other users of Linde equipment have testified to its high efficiency and economy.

Machines made for plants big or small. Our new Vertical Enclosed Type machines are suited for plants from 1 to 30 tons. Then for heavy demands, calling for loads up to 300 tons, our horizontal type is guaranteed to give better service than any other refrigerating equipment on the market.



Linde Equipment Installed in Civic Abattoir, Toronto

Adopt Linde equipment in the place of old and unsanitary methods. We keep a permanent staff of engineers in Montreal, Toronto, Winnipeg and Vancouver, both for erection work and emergency calls that may arise.

COPPUS TURBO BLOWERS EFFECT STEADY SAVINGS

In the modern plant of the New York Ice Company, New York City, this 22" COPPUS Turbo Blower has been saving time, money and labor ever since installation in April, 1917. It has made possible the use of cheap fuel, and made sure the maintenance of constant steam pressure. So satisfactory has been the service of this COPPUS Blower that two more blowers have since been purchased for other plants of the New York Ice Company.

COPPUS Turbo Blowers are cutting down fuel costs and keeping up steam pressures in cold storage and artificial ice plants all over the country. Automatically regulated, self-oiling, quiet-running—COPPUS Turbo Blowers are by far the most efficient means of securing mechanical draft.

Let our engineers tell you just what COPPUS Blowers can save you in your boiler room. Write for Blower Catalog.

STRENGTH—GOODNESS—QUALITY

Performance Facts of
Durabla Gasket Material

Tight joints are made and maintained by DURABLA under the following severe services and conditions:

Steam:	275-300 lbs. pressure; 275°-300° superheat.
Oil:	Pressure still joint re-made over 160 times.
Gasoline:	Cylinder heads of gasoline engines and pumps.
Acids:	All acids that can be carried in pipe lines.
Water:	Equally satisfactory with temperature of 40° or 210° F., at any pressure.
Ammonia:	Both absorption and compression systems of refrigeration.
Air:	Air lines and cylinder heads of compressors—all types.

One Standard material for all gasket work—Sold on a Service Basis

DURABLA is sold in sheet or gasket form and the trade mark is stamped all over the material.

Turning a Loss Into a Saving

Before Detroit "V" Type Stokers were installed

Higher coal prices made hand firing too expensive for the Mercer County Light, Heat and Power Company, Greenville, Pa.

To obtain more heat from the coal with the same natural draft their engineers installed four **Detroit "V" Type Stokers.**

The result is best told by Chief Engineer, R. L. Morsman, in the following statement:

"We compute that we are obtaining a saving of from 10 to 12 per cent of coal over previous hand fired method.

"We are obtaining a b.h.p. on approximately 3½ lb. of coal of 13,000 to 13,500 b.t.u. This is equivalent to a little better than 72% efficiency, which we consider very good for everyday conditions.

"The stokers are giving excellent satisfaction and we would be very glad to recommend them to your prospective purchasers."

Let us tell you what Stokers can do for you. Write for Catalog "P."

PUTS AIR TO WORK

THE NEW A-7 TURBINE-TRANSMISSION

A BRAND-NEW DRIVE FOR STOKERS—FANS—PUMPS

The cumulative experience of 60 years is expressed in the design and construction of this new unit. The unique features allow highest turbine efficiency while the stokers, fans and pumps are working at their most economical speeds.

The turbine is supported directly from the transmission casing—flexible couplings are eliminated—no sub-base is necessary—alignment trouble is impossible—and lubrication is automatic.

Much time has been spent in carefully designing this unit. Thorough tests were made in our shops long before anyone outside of our organization was asked to prove its merits under actual working conditions. For over a year a number have been in use, by several of our customers, with remarkable satisfaction.

It is with confidence and readiness that we ask you to acquaint yourself with the possibilities of this practically tested driver. You will find our Turbine Department always prepared to co-operate with you.

Plant Equipment of a Montreal Dairy

The Modern Dairy Finds Extensive Use for Power Plant Equipment for Steam Supply and Refrigeration—This Article Deals With That Installed in the Dairy of J. J. Joubert, Montreal

By J. H. RODGERS

WHEN the bottle of milk is taken from the doorstep in the morning how many stop to consider the process through which the contents have passed from the time it leaves the farm? Few of us, it might be said, give the matter a second thought, content that the milk is fresh and cool.

The plant of J. J. Joubert Ltd., of Montreal, while not an exceptionally large one, illustrates remarkably well the development that has taken place during the past decade, in the systematic distribution of milk to the rapidly growing urban populations. The original factory was established a little over fifteen years ago, and the operation of the plant at that time was amply provided for by a 2½ H.P. steam engine. The demands of the "milk trade," however, necessitated continued expansion, so that the initial equipment has been augmented from time to time, and the present requirements call for steam heating capacity of 200 H.P. and the electric motors, for the operation of the machinery, aggregate 250 H.P. The first refrigerating unit was installed about ten years ago, it being a Linde Canadian machine of 25 ton capacity and operated on the direct expansion system, the reservoir and the piping having a capacity of 1,500 gallons. The second installation was made about six years ago and consisted of a 65-ton Canadian ice machine, operated on the direct expansion system, provided with two reservoirs, which with the piping, had a capacity of 3,125 gallons, the chambers supplied being maintained at a temperature ranging from 26 to 38 degrees F., with a separate room for ice cream kept at a temperature of 10 degrees above zero. This 65-ton machine likewise provides for the making of 13 tons of artificial ice per day. The heavy demand for ice cream made it necessary to add still further to the refrigerating equipment and the latest installation, made a couple of years ago, consists of a 50-ton Linde Canadian machine, which is exclusively devoted to the making of ice cream, the other two units being used for general refrigeration and pasteurizing purposes.

A Drysdale centrifugal pump is used for forcing the water through the condenser to the brine tank located on the roof of the building, 90 feet above the level of the pump. Rochester force feed lubricators are fitted to all of the ammonia and air compressors.

Owing to the varied sources of supply the modern city dairy requires to exercise the greatest care when accepting milk at the factory. Both the cans and the contents are subjected to the most rigid inspection as soon as they are placed on the platform. The cans in particular are closely examined by the inspector and suspicious containers are handed over to the chemist, who makes a thorough analysis of the contents, and if the milk is polluted in any way, the can and the contents are confiscated and the shipper immediately notified of such milk.

After the milk has passed inspection it is filtered through a fine mesh strainer before being pumped to the storage tanks, which are specially equipped for prompt cooling. From here on the modern pasteurizing of the milk takes place.

Dairy engineers have solved the problem as to how large quantities of milk may be pasteurized. It is a difficult thing to raise thousands of gallons of milk up to the required temperature, maintaining it at that heat for a specified time, and again cooling it to the temperature of cold water. Before commencing the actual pasteurizing process, the milk, as it comes from the storage tanks, passes through a DeLaval power separator for clarifying purposes and separating the different elements, the cream and the milk being divided and drawn from the chamber through separate outlets. All solid particles and sediment are retained in the machine so that the milk is left clear and clean. This installation is shown in Fig. 2.

It will be seen that the separator is elevated on a concrete base so that the milk, after clarifying, flows directly into the top of the pre-heater in which it is raised to a temperature of about 125 degrees F., the milk being in motion at all times. Steam coils are used for heating the milk and regulators are provided for keeping the temperature of the milk constant. From the pre-heater the milk passes to the pasteurizing vats, shown in Fig. 3, where the temperature is raised to 145 degrees F., the flow of the milk being such that its duration in these vats will be about twenty minutes.

For correct and effective pasteurization it is essential that closed vats be adopted and the milk kept constantly agitated during the process so as to prevent the formation of scum or "scalded layer"—a condition that serves as a

FIG. 1—LINDE CANADIAN 50-TON REFRIGERATING MACHINE, MOTOR DRIVEN.

good protection to tubercle bacilli and enables them to resist a higher temperature than otherwise would be fatal to them. At a temperature slightly above 150 degrees F., milk begins to acquire a cooked flavor which is often objectionable, so that the J. J. Joubert Company have adopted a maximum temperature for pasteurization of 145 degrees F., for a period ranging from fifteen to twenty minutes and under constant agitation. This latter is accomplished by means of a helical pipe coil passing through the centre of the vats, and through which coil the steam for heating the milk is passed. Individual motors of 5 H.P. are provided for agitating the milk. Thermometers and indicators are fitted to each vat to register the temperature and the level of the milk.

To complete the pasteurization it is necessary to lower the temperature of the milk to about 45 degrees as quickly as possible. This is accomplished by means of refrigeration and the method employed at this plant is that of the double-pipe condenser, shown to the rear of the pre-heater in Fig. 2. The milk is drawn from the pasteurizing vats and by means of the small pump shown at the left of Fig. 2, is forced through the inner pipes of the condenser, the liquid ammonia

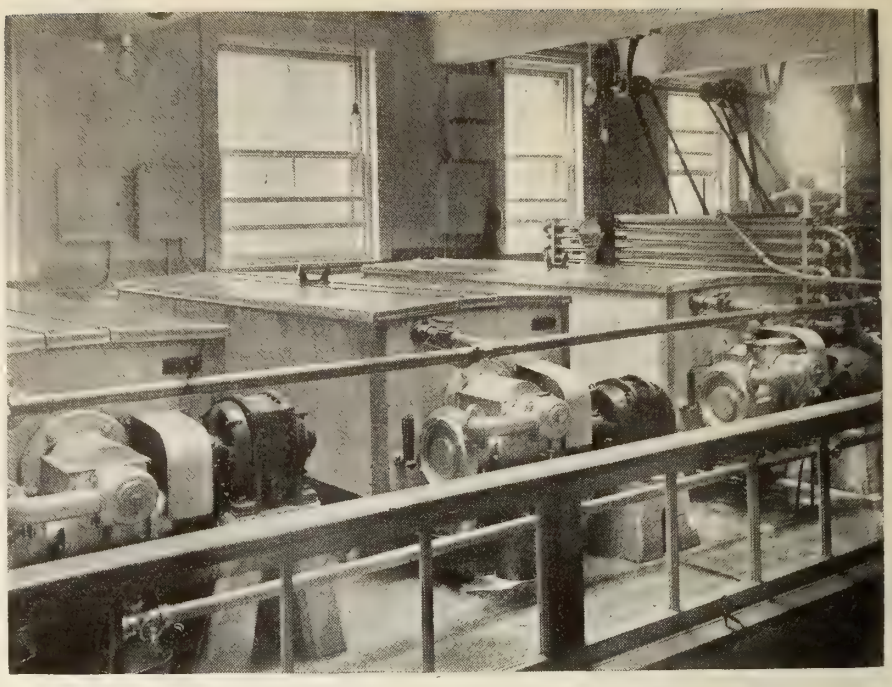

FIG. 3—PASTEURIZING VATS FOR MILK, WHERE IT IS KEPT AT A CONSTANT TEMPERATURE OF APPROXIMATELY 145° FAH.

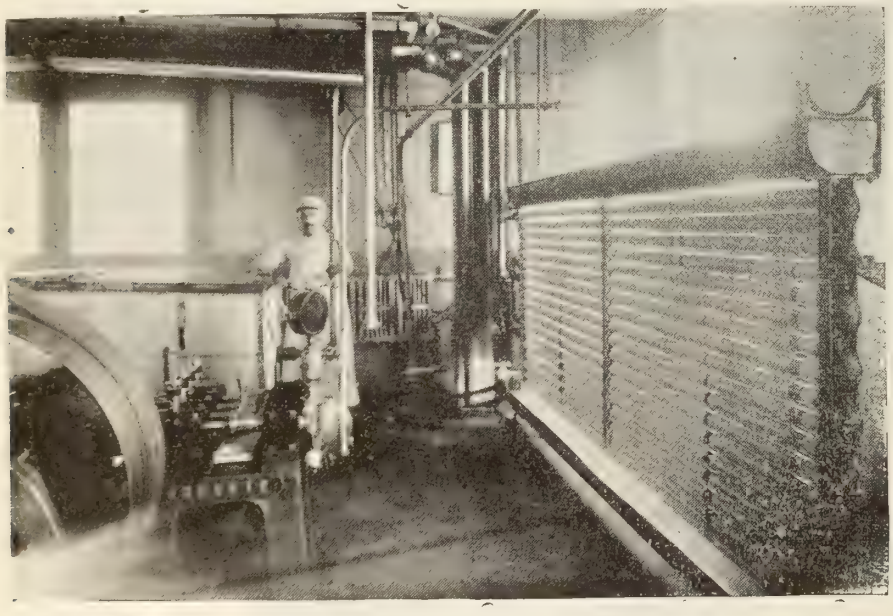

FIG. 4—PASTEURIZING VAT, CIRCULATING PUMP AND COOLING COILS FOR CREAM

in the outer or surrounding pipes absorbing the heat from the milk, so that the latter passes from the refrigerator coils at a temperature of 45 degrees F.

WHEN MERCURY FREEZES TO STONE AND RUBBER GROWS BRITTLE

By F. H. Sweet, in "Tycos"

Among the marvels of science which go to prove the saying that truth is stranger than fiction, none can be more curious, interesting and instructive than the phenomena of liquefied gases and, more specially, liquid air. For although scientists had predicted the possibility of its existence before the liquefaction of air or any other gases had much more than been thought of, it was only after a struggle of many years on the part of physicists that the first drop of liquid air was born, and this was but a mist appearing in a glass tube for the fraction of a second. It is a Frenchman to whom belongs the honor of first producing liquid air, which he succeeded in doing December 2, 1877, by accidentally opening a wrong valve on his apparatus. The infinite amount of patience, toil and ingenuity represented in the subsequent research and following up of those few drops of transient mist is seldom thought of now, since liquid air has become one of the commonplaces of this ultra-scientific age.

Liquid air, as it is now known, is manufactured by a process of alternate compression and expansion, the latter producing the enormous cold necessary to liquefy air. Powerful machines first compress the air to several thousand pounds per square inch; this air is then allowed to expand through a jet, and since even the cold thus produced is vastly insufficient to cause it to liquefy, the

FIG. 2—SEPARATOR, PREHEATER COOLING COILS AND CIRCULATING PUMP.

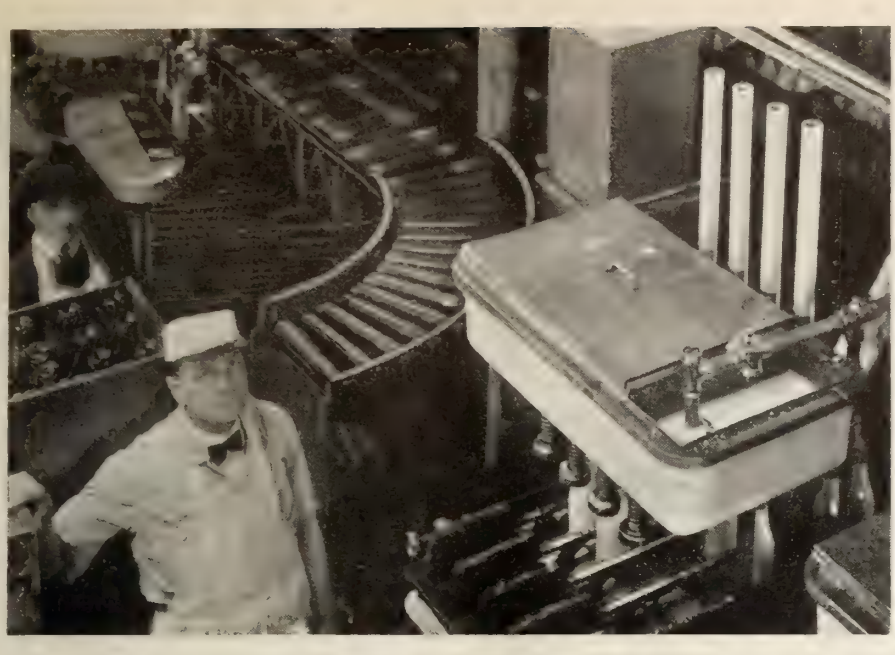

FIG. 5—BOTTLE FILLING AND CAPPING MACHINE.

air is ingeniously made to cool itself by passing through a tube, just before it reaches the expansion nozzle which is surrounded with another tube through which the expanded and therefore cooled air from the nozzle is caused to pass. This, of course, cools the incoming air, so that when it expands it becomes still colder and cools the entering air still more, which goes on until the air liquefies. The apparatus with various elaborations and embellishments, constitutes the basis of all the commercial processes for liquefying air, which is manufactured rather extensively to secure oxygen and nitrogen from the atmosphere. The most recent achievement in liquefying gases is the success with helium, the most refractory gas to liquefy known, and by its aid reached a temperature within three degrees of absolute zero.

Liquid air, then, is nothing but air cooled by expansion until it condenses to a liquid, the same as steam cooled below 212 degrees F. will condense to liquid water, and it contains the same constituents as atmospheric air; oxygen and nitrogen. But it is intensely cold,—193 degrees C., or about 320 degrees below zero, Fahrenheit, and therefore, is in a veritable furnace all the time, but just as water will not rise above 212 degrees, no matter how hot its surroundings are heated, liquid air remains at its boiling point of—193 C., although evaporating rapidly, as water would do under the same circumstances. To prevent this evaporation, special containers must be used—flasks with two walls and a vacuum between them to prevent the conduction of heat to the liquid air, and silvered to prevent radiation of heat as much as possible, in reality, a thermos bottle. Such a flask, called after its inventor a Dewar flask, is used with satisfactory success.

We have spoken of the evaporating of liquid air, and given its boiling point as —193 C. Now the two components of liquid air mentioned above have not the same boiling point; nitrogen is harder to liquefy of the two, that is, the more volatile, and therefore it evaporates first, when liquid air vaporizes. Liquid air is therefore always becoming richer in oxygen until it becomes pure liquid oxygen, deep blue, and boiling at—182C. This means that liquid air is practically always richer in oxygen than normal air, and it is to this fact that many of its peculiar effects are due.

These facts are taken advantage of in the processes for making pure oxygen and nitrogen from air, which forms by far the most important commercial application of liquid air, for an elaborate apparatus for rectifying the liquid as it evaporates provides an unbelievably cheap way of separating air into pure oxygen and nitrogen, due to the difference in boiling points of the liquids. This fractional evaporation is shown by this pretty experiment. Liquid air is poured into a glass of water, and, as by curious coincidence the density is almost exactly that of water, the nitrogen slightly lighter, the oxygen heavier, the globule will first float upon the surface, then, as the nitrogen evaporates, it will gradually dip below and finally sink when it has become pure oxygen.

Strange as it may seem, the water will not be frozen during this experiment. For while it is very cold in degree, liquid air contains no large quantity of cold; it is only another paradox of these extreme temperatures that a pound of ice should furnish nearly twice as much cold in melting as a pound of liquid air does in evaporating, for while the cooling by liquid air is performed at a much lower temperature, it is significantly less in quantity, and entirely insufficient to overcome the high specific heat of water and freeze a quantity of this liquid larger than its own volume, fiction writers to the contrary.

This brings us to the subject undoubtedly more interesting to the layman, though fortunately not the only achievement to the credit of liquid air, that is, the effects of its remarkably low temperature. Nearly all liquids and even in liquid air are frozen to a block which can be used to drive nails. Alcohol, or better still, wine, is frozen to a solid which may be eaten with a spoon while in the pasty stage. While this list could be extended indefinitely, we must consider in our limited space the modifications of solids, which are none the less interesting, in liquid air.

A flower assumes the consistency of porcelain after a moment's dip, and is broken by a slight tap, a piece of rubber tubing becomes as hard as a rock, and easily broken into pieces, and a tender beefsteak is capable of breaking plates, or, stranger still, of driving a nail made of mercury. Naturally liquid air has the same effect upon our flesh. The sensation is that of a burn, and a few seconds converts a finger into a very brittle yellowish stick, very easy to knock off.

If we use in our experiments liquid air which has partly evaporated, and, therefore, consists largely or entirely of liquid oxygen, new possibilities present themselves. The great vigor of combustion in oxygen is well known, and combustibles burn with unaccustomed brilliancy in the gases vaporizing from liquid oxygen. It might be assumed, however, that combustion in so cold a medium as the liquid itself would be impossible, but the combustion of, say a match, is greatly accelerated by plunging it into the liquid, and the highest and lowest temperatures can coexist without the least difficulty. An arc carbon heated red-hot and plunged into liquid oxygen burns tranquilly, giving off an intense glow of light and heat. Other combustions of this nature are less docile. Cotton waste dipped in oxygen deflagrates in the manner of guncotton in the open air, and if confined, explodes with equal violence. Cartridges made of charcoal and similar combustible materials, and impregnated just before use with liquid oxygen have been used with fair success in the place of dynamite, so fierce and rapid is the combustion of the carbon with this liberal supply of oxygen, although supplied at such a low temperature. Magnesium, phosphorus and petroleum are other combustibles which burn so rapidly in liquid oxygen as practically to constitute an explosion. Of course it should be understood that liquid oxygen alone is entirely devoid of explosive properties; it is only the combustions provoked with its aid that partake of this nature.

The industrial applications of oxygen in these connections are many and numerous, the oxy-acetylene cutting and welding torch being the most familiar, and as mentioned above, the gases secured by evaporating liquids rich in oxygen are compressed in steel cylinders for distribution to the trade.

Liquid air cannot be preserved in closed vessels, since it is the small evaporation always taking place which keeps it cold, and if not free to communicate with the atmosphere, it rapidly vaporizes, until entirely evaporated.

Explosions in Ammonia Refrigeration Plants

Explosions in Refrigerating Plants Are Somewhat of a Rarity, But the Engineer Should be Well Aware of Their Possibility— The Writer Points Out Their Possible Origin

By W. C. KLOTZ

THE possibility of explosive accidents, while fortunately of infrequent occurrence, is nevertheless ever present in a refrigeration plant. They may occur at any time through unforseen and apparently remote causes, so that too much care cannot be exercised in the handling and running of all apparatus connected therewith. The collection of data and study of explosions that have occurred, has shown how divergent these causes may be, and has at the same time, in many instances, pointed out the way of avoiding such conditions in future.

Ammonia gas by itself is neither inflammable or explosive in air, nor are mixtures of air and ammonia explosive, but the gases of a refrigeration system, consisting as they do of ammonia gas with varying amounts of oil vapor, hydrogen, etc., can be decidedly so. Explosions have been noted to occur, not from the sudden release of gas due to a breakage, but from the subsequent ignition of the mixture of gas and air in contact with an open flame. An example of this is shown in the case of a large compressor in which a cylinder head was forced out, due to the breaking of the follower plate of the piston. The gases escaped into the room, and coming in contact with an open light, ignited. The resulting explosion wrecked the machinery, and was followed by a fire which finished the work of destruction. Another similar accident was one in which the bypass valves of a large compressor gave way, allowing the escape into the room of a quantity of gas. In this case, the explosion did not occur for several minutes after the escape of the gas, and was apparently caused by ignition from an electric arc light hanging near. A different condition was that of an oil-cooled compressor in which the sight glass of the oil reservoir broke, letting oil and ammonia gas be blown out. No subsequent explosion was recorded, but when the fumes were dispersed, and the room entered, evidences were found that a slight fire had taken place, as the paint on the walls was found blistered, and some loose papers on a desk were burned.

But that an explosion can take place in a compression system itself without the presence of ammonia is shown by an accident that occurred while testing out with air pressure. The compressor had been undergoing repairs and was being air tested, when at 250 pounds the oil separator exploded with great violence. The explanation advanced was that the superheated air, forced from the compressor into the oil separator, which apparently was not clean, formed an explosive mixture with the oil vapor, which automatically ignited with disruptive force, severely injuring several persons.

Explosive accidents to absorption systems that have been noted, have been largely due simply to overpressure, resulting in the violent fracture of the generator or other parts, and have been traced generally to defective parts, or negligence. Such an accident occurred some years ago resulting in the death of five persons. It was found subsequently that the safety valve had been removed and not yet replaced. There is, however, an amount of hydrogen formed, apparently by decomposition of ammonia at high temperature in the generator, or else by hydrolysis, which finds its way to the top of the condenser. The gases from the purge line may be ignited at almost any time, burning with a yellowish flame. Formerly this inflammability was attributed to a supposedly impure ammonia, but the condition is found to exist irrespective of the kind or quality of ammonia used. A sudden release of this gas in quantity under the proper conditions is quite able to produce explosion when ignited, and in fact experiments have been made with certain proportions of such gases with air which have been made to explode at will.

The theory that lubricating oil in a compressor can be sufficiently vaporized to produce a source of danger is a reasonable one when the conditions are taken into consideration. Ammonia compressor oil, having a low cold test, generally has a flash point of 300 deg. fahr. or under. At such temperatures ignitable volatile vapors are given off by the oil, and the rapid passing back and forth of the compressor piston releases, and mixes the oil vapor with ammonia gas, the mixture passing out of the compressor. When mixed with the proper proportions of air, it can quite readily form a highly explosive gas.

The conclusions to be drawn from the study of ammonia plant explosive accidents and their causes are that, except for overpressure, an explosion within the system is very unlikely under running conditions, and the explosive result of a sudden discharge of the working gases into the atmosphere without contact with open lights or fire, is not probable. On the contrary, the contact of fire with such gases in the atmosphere, in a restricted space, can and has produced most disastrous results. This makes it imperative to allow no open flame of any nature within range of a working plant. Further, costly experience has shown that, before testing out a plant with air pressure, it is necessary to be absolutely certain that the tested parts are clear of oil, so that no combination of superheated air and oil vapor can have a chance to accumulate.

That explosive accidents are so few is due, not so much to the care with which plants are operated, as to the fact that fortunately all the necessary conditions are only infrequently at hand, for if every "blow-out" meant a corresponding explosion, the history of ammonia refrigeration would be vastly different from what it now is. Finally, it is most essential that strict watch is kept on the whole system from end to end in all details, as the failure of even an apparently unimportant part has been found sufficient to cause general havoc, and even fatality.

When a liquid is heated in the vessel which contains it, there is an apparent expansion which varies with the nature of the vessel, so that, in order to determine the absolute expansion, a double measurement must be made, the apparent expansion of the fluid being modified by the previous measurement of expansion of the container.

The "Revue de Chimie Industrielle" gives the following report of a much more direct process evolved by M. Jean Escard, which requires only one operation.

He makes use of an apparatus composed of two concentric cylindrical containers, the inner one of copper and the outer of glass. The inner container has a volume which is exactly half that of the outer one. But it is a known fact that the co-efficient of expansion of copper is 0.000,0172, while that of glass is only 0.000,0086, i.e., exactly half. Consequently, when the two containers are heated at the same time there is no change in the volume of the space between them, since the inner one has an expansion which is double that of the outer vessel having a double volume. Thanks to this ingenious compensation, a single reading enables us to calculate the co-efficient of expansion of any liquid whatever occupying the space comprised between the two vessels.

The combination is placed in a water-bath, which is heated from the outside. This has a ring-shaped cover containing two holes, in one of which is inserted a thermometer which fits tightly and which indicates the temperature attained by the liquid being tested. In the other hole is placed a graduated tube welded to the glass and having a very narrow channel so as to make it extremely sensitive. The liquid expands into this, and its expansion is measured directly and without significant error

The Absorption System of Refrigeration

The Following Article is Descriptive of the Functioning of the Absorption System of Ammonia Compression—The Absorption System is Apt to Appear Complicated to the Engineer at First

By JAMES F. PATTON

MODERN cold storage practice demands refrigerating machinery capable of producing and continuously maintaining, with high economy both of fuel and water; very low temperatures as compared with those of a few years ago—and this is true whether ammonia or brine be used as the medium of circulation. The latter is now generally used on account of the ease of regulation of the temperature and because of its safety. Brine temperatures of 15 to 25 degrees below zero are common, and by the use of calcium chloride or special coolers this point may be greatly exceeded. The absorption system of refrigeration is particularly adapted to cold storage work, but its operation is a mystery to many of those who are thoroughly familiar with the operating principle of the compression system. In these latter days when the cost of fuel and labor is advancing continually and the cry of "Profiteer" is heard in the land, economical operation is important; but of even greater importance is the selection of the system to be used for any given work. Ice-makers have found out that there are but two practical methods of manufacturing artificial ice—the compression and absorption. Each system has its advocates and its advantages and it is not the object of this article to enter into any discussion or to advocate the selection of either type for any given work. But as a large percentage of the plants now in operation are run on the compression principle, and as most of the articles which appear in the magazines from time to time relate to that system, a discussion of the absorption system may be of value. This system operates on well-known laws and when once these laws are understood the absence of the massive, complicated and highly polished engine used in the compression system is easily explained. The cycle is as follows : 1st.—The liberation of an-hydrous gas from aqua ammonia in the generator by means of heat. 2nd.—The liquefaction of this gas in the condenser by removing the heat with the condensing water. 3rd. — The expansion of this liquid through the freezing tank coils—thereby absorbing heat from the brine in the tank. 4th.—The reforming of the original solution of aqua ammonia in the absorber and the return of this solution to the generator. The fact that water and ammonia have a great affinity for each other is the foundation on which the entire system is based. At 50 degrees one volume of water will absorb 900 volumes of ammonia gas, while at 100 degrees it will take up over 450. When a liquid can be vaporized readily and the resulting gas can be readily absorbed by another liquid, we have the conditions for the successfud operation of an absorption system. Fig. I. shows a modern absorption plant. Steam being turned into the generator will gradually heat the ammonia to the boiling point and the ammonia gas which is generated passes to the analyzer or rectifier (E) which is directedly over the generator. This consists of a series of deflecting pans or plates over which the hot gas must pass for the purpose of separating any water which may have been carried over with the ammonia gas. The water thus distilled is drained back into the generator. From the rectifier the gas passes to the condenser (F) which consists of a series of pipes over which water flows, cooling the dry gas, which liquifies under the generator pressure. The liquid ammonia flows to the receiver (G) under pressure and is expanded into the freezing coils through an expansion valve (H) circulating through the coils and absorbing heat from the brine. It is then passed to a coil in the tank which contains the water for the cans and as this water is materially reduced in temperature, the efficiency of the plant is raised to a considerable extent. From the distilled water tank the gas passes on to the absorber (D) which performs a reverse operation to that performed in the generator. Heat supplied in the generator separates the ammonia from the solution, leaving what is called "poor liquor"; in the absorber the weak aqua ammonia entering through a spray pipe at the top absorbs the gas which comes from the distilled water tank. The pressure produced by the formation of gas in the generator forces the poor liquor out through a coil in the exchange and

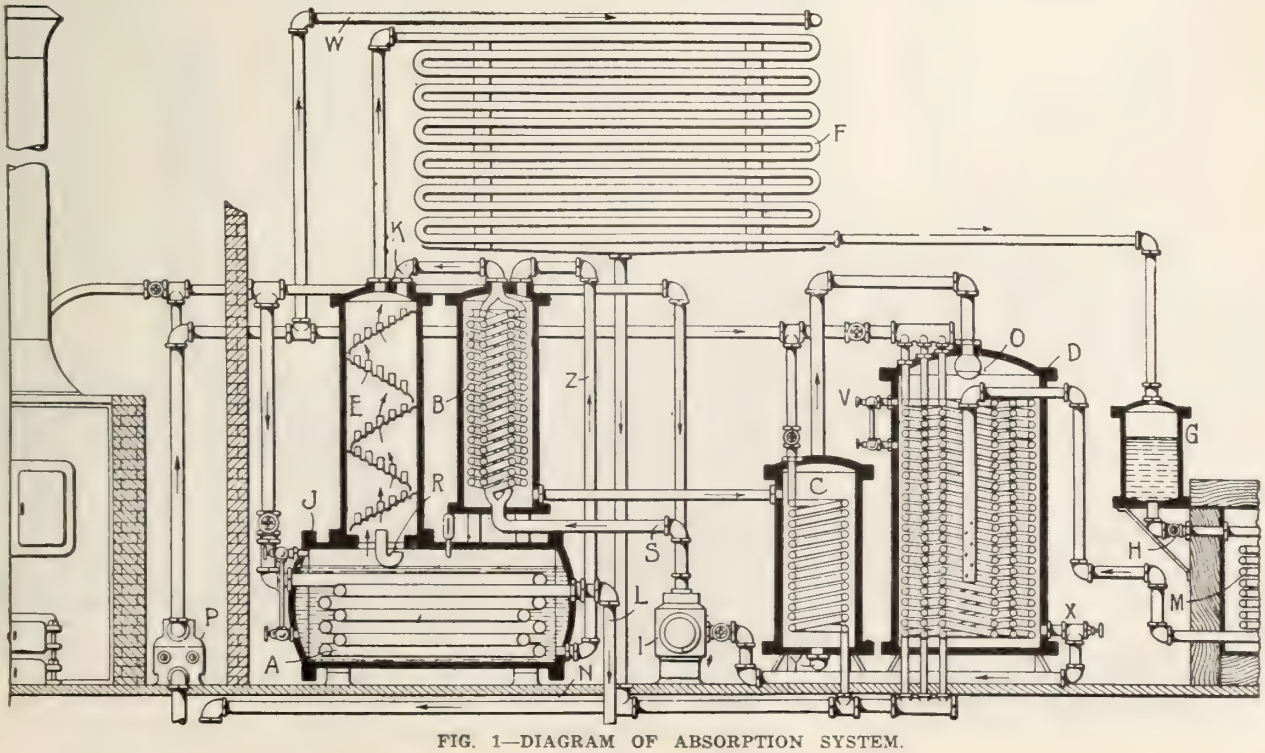

FIG. 1—DIAGRAM OF ABSORPTION SYSTEM.

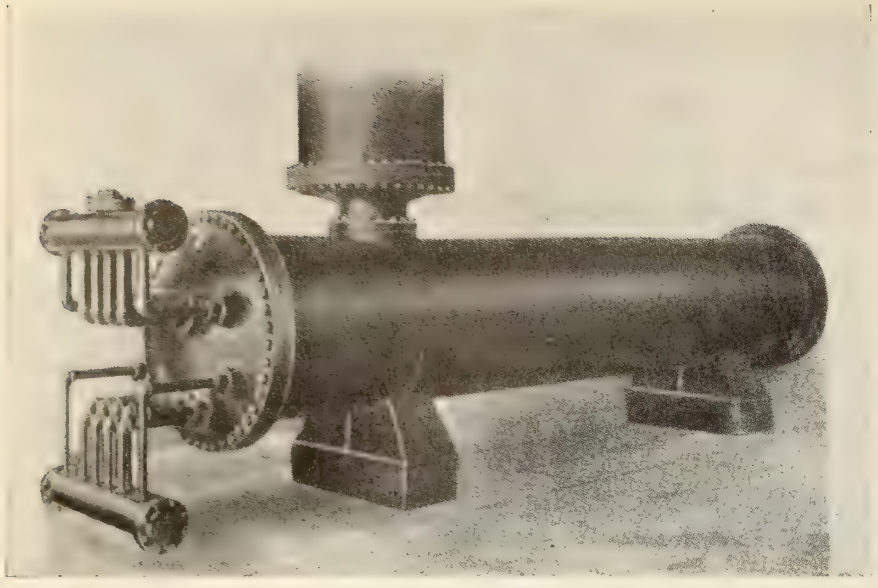

FIG. 2.

on to the absorber from which it goes back to the generator, through the pump. The absorption of gas is rapid and continuous, the rich liquor being drawn off from the bottom of the absorber by an ammonia pump (I) and forced through the exchanger (B). This consists of a drum in which are several coils of pipe through which the liquid from the pump is forced. The coils are surrounded by the hot weak liquor which comes from the generator. This hot liquor, therefore, is made to give up heat to the rich liquor in the coils. The higher the temperature—the less the moisture removed by the liquor in the analyzer, and as dry gas governs the economy of the system more than any other factor, the horizontal generator has an advantage over the vertical as it allows much more exchange surface. Generators are constructed in various forms, both horizontal, as shown in Fig. 2 and vertical as shown at (X) in Fig. 3. The horizontal is the more expensive, but has the advantage of supplying dryer gas. In the vertical type the evaporating surface is small and the boiling rapid, therefore, it is hard to keep the steam coils covered with liquid. The coils when uncovered become pitted by the action of the gas and ammonia liquor and the vertical type will boil over if forced. Also as shown in Fig. 3 the height of the apparatus is excessive when it is combined with a rectifier. However, in many installations the rectifier is now being omitted as some engineers claim that the benefits resulting from its use are not sufficient to pay for its installation. So the last objection to the vertical type generator has little weight. The atmospheric or surface type condenser, shown in Fig. 4, consists of a series of wrought iron pipe coils through which the ammonia passes being cooled by water which flows from the sprinkler troughs shown. This is a simple and efficient form, but in some cases the building construction will not permit its use while in other cases the splash from the condensing water may be objectionable. In the double pipe condenser, shown in Fig. 5, the gaseous ammonia enters the space between the inner and outer pipes, the water flowing through the inner pipe. In the shell and coil type the water flows through the coils while the ammonia circulates at the top of the shell—is cooled and condensed and leaves from the bottom. This construction reduces the vapor friction to the lowest possible point, thereby, keeping the pressure close to that theoretically desired. The selection of the proper type is largely a matter to be governed by local conditions. When the condensing water is of a hard scale forming nature the efficiency of a double pipe system will be greatly reduced, while the efficiency of an atmospheric type will be greatly increased if it is used in an excessively dry climate as there is considerable evaporating effect due to the water flowing over the pipes. There are many types of absorber, but in general they may be classed as "full" or "empty" —according to their method of operation. In the first type the liquid and gas are admitted at the bottom and the gas must pass through the entire body of liquid in the shell—which of course gives almost perfect absorption, but there is a loss of pressure equal to the head of liquid between the top level of the liquor and the gas inlet. In the "empty" type as already mentioned—the gas enters at the bottom and meets the poor liquor which is sprayed in at the top. As successful operation depends to a great extent on the strength of the rich liquor supplied to the generator, it is desirable that this be as contant as possible. This regulation is easily obtained in the "full" type systems, but when the empty form is used, satisfactory results can be obtained only through the use of special regulators which keep the density between 16 degrees to 18 degrees Baume. The power required for an absorption machine may be calculated as follows: First determine the heat required in the generator. This is equal to the heat lost in the condensing coils minus the heat gained by the ammonia pump. The heat lost in the condenser is equal to the temperature of the gas which enters it minus the temperature of the liquid ammonia plus the latent heat of ammonia. This latent heat is difficult to find, but it may be calculated approximately by the rule:

555,5 — (.613 × temp.) — (.000219 × sq. of temperature).

The loss in the absorber is the sum of that produced by the absorption of 1 lb. of ammonia by the weak liquor and that which has been brought into the absorber

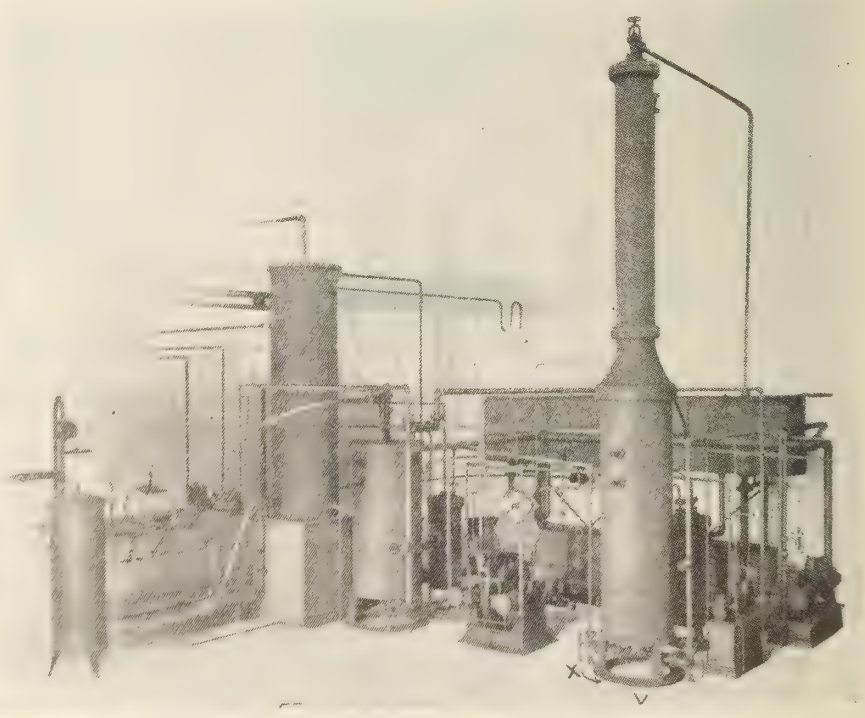

FIG. 3—GENERAL ARRANGEMENT OF ABSORPTION PLANT.

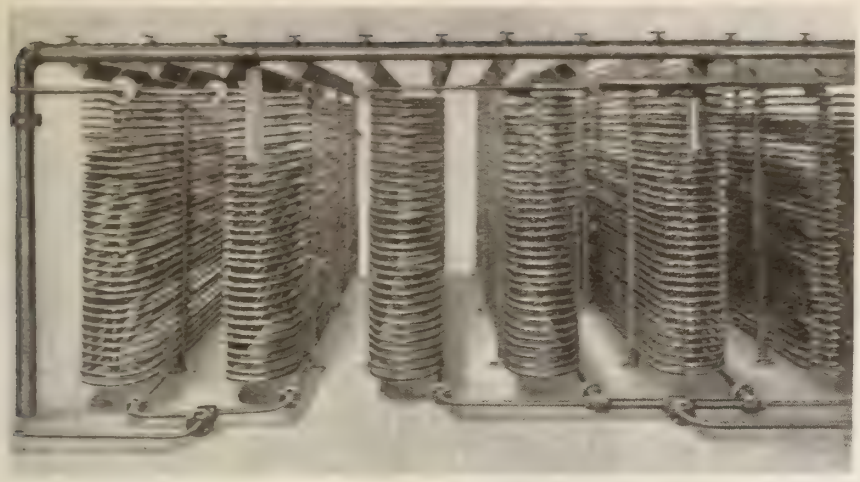

FIG. 4.

by the poor liquor, plus the negative heat produced by one pound of gas from the cooling coils. This latter is equal to the difference in temperature between the rich liquor going out and the gas in the coils, multiplied by .5. The heat which is brought into the absorber is equal to the number of pounds of rich liquor for each pound of active ammonia minus one times the difference in temperature between the incoming poor liquor and the outgoing rich liquor. The heat absorbed by one pound of the refrigerant in the cooling coils equals the latent heat of ammonia plus the difference in temperature of the ammonia liquid and the refrigerator, multiplied by the specific heat of ammonia. The heat produced by the pump is ordinarily disregarded but may be found by the rule.—Heat produced is equal to weight of rich liquor pumped multiplied by the difference between the height in feet of a column of water 1 sq. in. in area which will give the pressure of the absorber. This result is to be divided by the specific gravity of the rich liquor multiplied by 778. The weight in pounds of rich liquor circulated in an hour is equal to the pump cylinder area is square inches multiplied by length of strokes in inches multiplied by number of strokes per hour divided by 27.7 multiplied by the specific gravity of the liquid. This gives the B T U required per hour in the generator which is divided by the latent heat of steam corresponding to the generator pressure in order to find the number of pounds of steam required.

The steam consumption for the auxiliaries is found as follows: Multiply together the square of the cylinder diameter in inches, the length of stroke, the number of strokes per minute and the weight of one cubic foot of steam at the initial pressure. The result is the steam consumption per cylinder. Add to this the weight of steam required to distill the ammonia, and divide the result by 13.8 and the number of square feet of heating surface in the boiler is obtained.

Preliminary to charging and putting a plant in operation, it must be tested under pressure for leaks. This is done by connecting the suction of the ammonia pump to a water supply and pumping water into the system until full, and a pressure of 150 pounds is had. Inspection is then made for leaks and, if everything proves tight, the pressure is increased gradually to 300 pounds of something more. This pressure is maintained for at least half an hour while careful inspection of all joints is made. While the pressure is on, the valves on the gauge piping connections are closed and the gauges disconnected and cleaned by blowing out. Drains are then opened and the water allowed to flow out of all parts of the system except from the generator, which is left half full.

Steam pressure of 50 pounds is then turned on the generator coil, which results in a pressure of 30 pounds in the generator as soon as the water is heated and sufficient steam made to fill the high pressure side. At this stage the valves on the weak liquor pipe to the absorber are opened and the pressure forces the water from the generator to the absorber. The suction of the ammonia pump is now connected to the absorber, and the water and steam circulated through the system, while the vent cocks are left open so that all parts are thoroughly cleaned and blown out. After this has gone on for an hour or so, the pump is stopped, the steam shut off the generator coil, and the system allowed to cool. As soon as steam stops coming from vent cocks, they are closed, and the stop valves separating the various parts of the system are closed so that, on vacuum if formed in different parts by condensing steam, a leak in one part could not affect the rest of the plant.

With the system under a vacuum, as after steaming out, aqua ammonia may be forced into the generator and absorber by atmospheric pressure. Otherwise, the ammonia pump must be used to fill the two parts of the system—one after the other. An auxiliary suction makes connection to the pump, and the end of the suction pipe is inserted in the 1½ inch bung-hole of an aqua ammonia drum to within 1 inch of the bottom. All valves on the discharge side of the pump are opened and the ammonia is pumped into the system, care being taken to keep the drum as cool as possible. The generator is filled to the working level, as shown by the gauge cocks, and the absorber is filled to the top of the gauge glass. The ammonia pump is now connected with its suction to the absorber; all valves are adjusted for regular working conditions with steam admitted to the generator coils; the ammonia gas generated is allowed to pass over to the condenser, over which cooling water is circulated. When the pressure is about 120 pounds on the high side, the ammonia pump is started slowly, and the liquor level in the absorber is gradually reduced to the normal about mid-height of the gauge glass. With cooling water circulating through the absorber coils and the weak liquor cooler, the plant is in full operation.

When in operation with a normal charge the gauge glasses should indicated the following conditions:

The generator should have from one to two inches of liquid covering the coils. The amount in the absorber depends on the type used. In the tubular the level of the liquid should be at least one inch above the top of top row of tubes. In the atmospheric or double pipe type there should be about 12 inches of liquid in the receiver above the pump suction connection. In the shell type which runs empty the glass should show the liquid

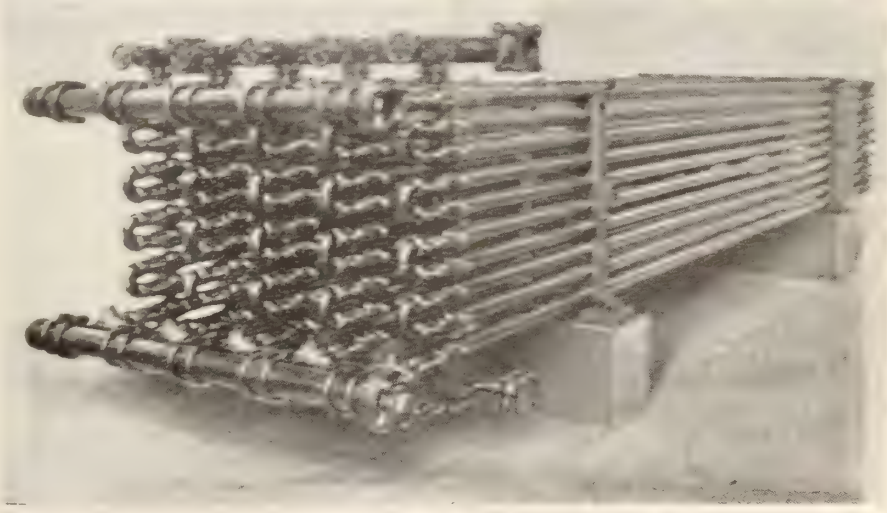

FIG. 5.

The Indication of the Ammonia Compressor

A Good-Looking Indicator Card is Not Always a Sure Sign of an Efficiently Working Compressor—The Writer Shows How to Determine the Isothermal and Adiabatic Lines and From Them to Judge of Operating Characteristics

By F. F. McNEIL

NO matter what book you pick up that deals with refrigeration and ammonia compressors, they always state, for capacity keep the back or suction pressure as high as possible. I have always found that for every temperature in the evaporating coils we have a corresponding pressure, and in the dry gas compressor we do not wish to run with the discharge pipe cold no more than we wish to run with it too hot, but we do wish to keep as much ammonia as possible in the evaporating coils. If you desire to run the compressor at a constant temperature on the discharge side, you will have a constant suction pressure and any variation from this pressure will mean a variation in the temperature on the discharge side of compressor, this means for a constant temperature of brine or room, but also applies to all brine and room temperatures, each temperature having a corresponding pressure.

Again they tell us it is bad practice to run a plant when short of ammonia. I fail to see how it is possible to run an ammonia compression plant when short of ammonia; the only plant that I ever saw run with any success when short of ammonia was one in which a shell type cooler was used, the shortage could then be detected by the amount of opening of the expansion valve as well as the gage glass on the receiver.

One of the best indications of lack of ammonia in the system is a constant variation of pressure and consequently temperatures; this is most noted by the constant variation of the temperature on the discharge side of the compressor which will vary up and down with the same brine or room temperature, and with the same opening of expansion valves.

Many engineers figure out the mean pressure of the indicator card and if it looks good they believe their compressors are o.k. and let it go at that. If you would get the best from the compression you should apply both the Isothermal and Adiabatic compression curves.

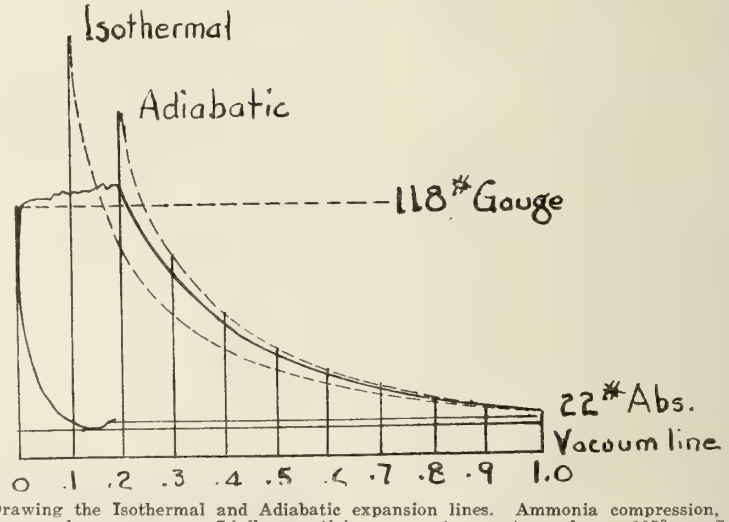
The curve the indicator pencil will trace should compression take place without heat is known as the isothermal curve but no means have this far been provided to remove the heat of compression as fast as it appears, therefore it is seen that if the compressor is in proper working condition the curve traced by the indicator pencil will be above this isothermal curve.

On the other hand, the adiabatic curve is the curve the indicator pencil would trace if there was no loss of heat due to compression, this is also impossible in the ammonia compressor and in order to use the least power possible per ton of refrigeration every means is used to keep this temperature down, it is now seen that the curve traced by the indicator is not adiabatic but must fall below it. The actual curve as traced by the indicator pencil from a compressor in good working condition will fall somewhere between these two curves, and that it will be somewhat closer to the adiabatic than the isothermal curve.

From the first laws of gases known as Boyles laws, we have (P. V. = a constant), in which P = absolute pressure and V. = volume.

That is, the product of the absolute pressure multiplied by the volume for any point of the stroke must be the same, the temperature, of course, remaining constant.

For example, below is an indicator "diagram" from one end of the cylinder of a 18½ in. x 30 in. ammonia compressor to which I have added these curves:



Drawing the Isothermal and Adiabatic expansion lines. Ammonia compression, 118 lbs., condenser pressure, 7.' lbs., suctioi pressure temperature of gas, 105° c. Scale of spring, 100 lb. = 1 in. Cyl. 18½" x 30" x 72 revo. per min. Area of card, 1.32 sq. in. M.E.P., 49 lbs.

In this case, the cylinder is filled with gas at a suction pressure of 22 lbs. absolute, the diagram is divided into ten equal spaces. Remember to use absolute pressures we have P. V. = a constant where P = 22, V = 1. 22 × 22, which is constant. Now for .9 of the volume we have 22 ÷ .9 = 24.4 lbs., likewise for .8 and, etc., to the .1. These results as found are measured off with a rule that is scaled to correspond with the indicator spring used, and laying the different pressures off on the diagram in their respective plans, we have a series of points through which the isothermal curve is drawn.

Computing the points through which the adiabatic curve is drawn, involves the use of logarithms, which are not understood by all engineers. The following table of adiabatic multipliers will make the operation very simple, and the results, although not absolutely correct, will be quite reliable.

Adiabatic Multiplier

Volumes in one-tenths parts.	Absolute pressure pounds per sq. inch.
1.00	1.
.90	1.147
.80	1.337
.70	1.590
.60	1.943
.50	2.462
.40	3.291
.30	4.783
.20	4.103
.10	19.953

The formula used for computing the adiabatic curve is $PV^{1.3}$ = a constant that is the product of the absolute pressure × the volume to the 1.3 power equals a constant, the 1.3 is the ratio of the specific heat of ammonia gas at constant pressure to that at constant voleum; specific heat of NH^4 gas at constant pressure is .3913 and at constant volume .508, therefore .508 ÷ 3913 = 1.3 approx.

The formula used in finding the higher pressure due to decrease volume is: $P_2 = P_1(V_1/V_2)^{1.3}$; $P_3 = P_1(V_1/V_3)^{1.3}$ and etc. This equation is solved by logarithms thus:

Log. P_2 = Log. P_1 + [(Log. V_1 — Log. V_2) × 1.3]; and so on for the other pressures.

For convenience use the above table, which, although not absolutely correct, is all that is necessary for accurate results.

These curves are aso used for air compressor cards only the constant is 1.41 for air.

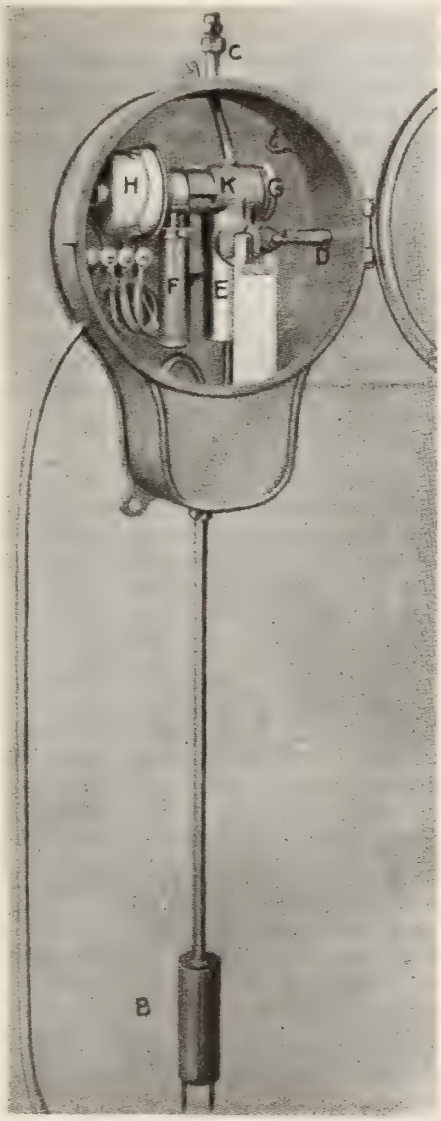
An example will explain the use of the above table, using the same diagram, we have 22 lbs. abs. pressure. Consulting the table we have volume one (1) has a multiplier of 1, thus $22 \times 1 = 22$ lbs. At a volume of .9 the multipier is 1.147 and $22 \times 1.147 = 25.234$ lbs. Likewise using the other volumes with their multipliers as .8, .7, .6, and so on, then by using the same scale and taking a measurement from the vacuum line as in the isothermal curve we have a series of points through which the true adiabatic curve is drawn.

The drawing of these curves is just the same for any suction pressure, the only difference is in using the new suction pressure and making sure it is absolute, that is, by adding 14.7 lbs. to the gage pressure.

How should the actual curve lie above the adiabatic curve? It would indicate that the pressure was too high due to gas leaking back through the discharge valves from the condensor. On the other hand, should the actual curve lie closer to the isothermal curve it would indicate not enough pressure due to leaky suction valves or a leaky piston. In closing, I wish to say that it does not pay to form an opinion too quickly as to whether a good looking card is the indication of a perfect compressor, apply the above rules and be sure.

A NOVEL CO_2 RECORDER

A novel electrical CO_2 recorder, which enables the percentage of CO_2 in flue gases to be determined by an electrical method, not involving the use of any chemical absorbent was exhibited by the Cambridge and Paul Instrument Co., Ltd., at the recent exhibition of the Physical and Optical Societies, states the "Engineer." The instrument has been tested under actual working conditions, and it is claimed it is both accurate and sensitive. It possesses the advantage that, while the portion of the instrument through which the gases actually pass can be placed in close proximity to the flue, the recorder may be some considerable distance away. If desired an indicator may be used instead of the recorder. The method employed for measuring the percentage of CO_2 is one devised by Dr. G. A. Shakespear, of the University of Birmingham, for testing the purity of gases. The composition of the flue gas is compared with that of air by means of an instrument known as a katharometer, which consists of two identical spirals of platinum wire contained in two cells drilled in a copper block, each of the spirals being connected to form one arm of a Wheatstone bridge circuit. If a fairly large current is allowed to flow in this circuit, the two spirals will become heated and will lose heat to the walls of the cells. The rate of cooling will depend on the thermal conductivities of the gases in the cells, so that if the two cells contain gases of different conductivities the two spirals will cool at different rates, and one will therefore be maintained at a lower temperature than the other. The difference in temperature of the two wires will cause a deflection of the galvanometer, the extent of deflection depending on the difference in conductivity of the two gases. If, therefore, one cell of the katharometer contains a pure gas and the other the same gas mixed with some other constituent, the extent of the deflection will be an indication of the amount of the second gas present, and



NEW CO RECORDER

the galvanometer can be calibrated to show directly the percentage composition of the mixture. The difference in conductivity between air and carbon-dioxide enables the method to be employed to determine the percentage of CO_2 in flue gases.

The engraving—Fig. 3—shows the katharometer and water aspirator, which are enclosed in a metal case with glass door. The katharometer H is screwed into the chamber K. The open cell of the katharometer communicates with this chamber, through which the flue gases are drawn by the water aspirator E. The other cell of the katharometer, which is filled with air, is connected to the tube F, which contains water, so that the air in the katharometer cell is kept saturated. The object of this arrangement is to prevent the water vapor in the flue gases from vitiating the readings, as it would do if the flue gases were compared with dry air. When the gas in both cells is saturated with water vapor the effect of the water vapor is the same on both sides and the readings are not influenced. Owing to the nearly equal conductivities of air and carbon-monoxide, the presence of the latter gas does not affect the readings. A filter box of glass wool for cleaning the gas which passes into the katharometer is attached to the screwed plug G. The water inlet to the aspirator is shown at D, and the pipe carrying the gas from the flue is connected to the tube C. A soot filter should be inserted between the flue and the tube C, and at the lowest point of the pipe a T piece with its end dipping under water should be provided as a drain for condensed steam. The U tube on the front of the aspirator is half filled with water, and when the aspirator is not working the water level in this tube will be quite steady and will indicate the chimney draught. The position of the water in the U tube also indicates the presence of any obstruction in the gas supply pipe, as this causes the water to be unusually high on the aspirator side. The water flow regulator B is designed to give maximum efficiency in the working of the aspirator. The flow is adjusted until water runs freely out of the fine tube at the bottom and only trickles out of the wider tube, which is an overflow pipe. The water consumption is about 5 gallons per hour.

The records are obtained by means of the company's thread recorder. This consists essentially of a suspended coil galvanometer in which the pointer is depressed by means of clockwork mechanism every minute or half-minute on to a thread impregnated with ink, which passes above the surface of a revolving drum carrying a chart. Between the times of marking the pointer is allowed to swing freely and take up its new position so that the succession of dots forms a record of the varying positions of the pointer. The charts are calibrated to read directly the percentage of CO_2. A 2-volt 40-ampere-hour battery is used to operate the instrument. Provision is made for testing at intervals the current flowing through the katharometer coils, and rheostats are provided to enable this current to be kept constant in spite of variations in the voltage of the battery.

A board of supervising engineers, composed of City Engineer Doucet, and Messrs. R. S. Lea and Walter J. Francis, consulting engineers of Montreal, has been appointed to prepare plans and supervise the work of completing the construction of the aqueduct that will eventually provide water supply for the city.

A High Pressure Rotary Compressor

A New Type of Compressor Recently Described in a Paper Before the American Society of Mechanical Engineers. High Volumetric Efficiency and High Ratio of Compression Are Obtained

By CHESTER B. LORD

ANY one familiar with the various lines of mechanical endeavor must realize that no vital change has been made in compressors in the last thirty years or more. While steam-engine practice has profited greatly by the development of the turbine, and generators and motors have been vastly improved, refrigerating machinery, at least as far as the compressors are concerned, has not been developed.

2. The same cumbersome reciprocating machines that were in use thirty years ago are being used to-day, with perhaps the difference that they are more cumbersome. There have been improvements in the way of better valves, a little higher speed and minor matters, of this kind, but none of them has changed the principle of the machine or resulted in any great economy either in weight, operating space required, or cost of installation. Any reciprocating machine, because of the very principle of reciprocation, must be built exceedingly heavy per unit of capacity and is confined to comparatively low speeds in operation. Because of this and its slow speed of operation, the power unit for driving such machines is of necessity also exceedingly heavy and cumbersome. High-speed machines such as electric motors and steam turbines are very rarely used because of the impracticability of connecting them directly to a large refrigerating machine.

3. Moreover, these machines require a great deal of attention, and necessary repairs are expensive because in almost every case the machines must be partly taken down in order to get at the parts to be repaired. Incidentally the repair parts, by reason of their size and expensive design, are very costly.

4. It may also be well to mention the many bearings that must be taken care

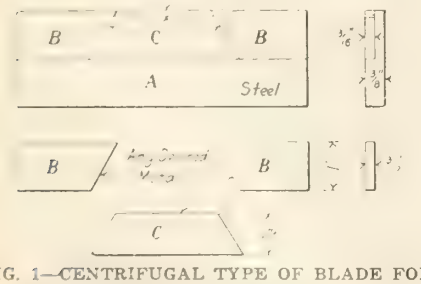


FIG. 1—CENTRIFUGAL TYPE OF BLADE FOR USE IN ROTARY COMPRESSOR WITH ECCENTRIC ROTOR.

of, the difficulty of lubricating them, and the delicate manner in which the valves must be adjusted in order to give best efficiency. All of these things combine to make the reciprocating machine very high in cost of installation, cost of operation and cost of maintenance, and hence in the mechanical world we are continually striving to get on a unidirection basis. We are replacing the reciprocating planer with a unidirection miller. In the place of the reciprocating engine we are introducing the uniflow principle. The automotive world is searching for the unidirection gasoline unit; and wherever possible reciprocating pumps and compressors are being replaced by the rotary type. The Patent Office records are full of rotary valves, rotary engines and rotary pumps. So much time and effort has been spent on them and to so little purpose that the rotary engine and compressor have almost been placed in the same category with the perpetual-motion machine.

5. From time to time the mechanical world has been startled or interested by claims of a perfected rotary engine, or its complement, a rotary compressor, and while all these attempts have been in the direction of perfecting the rotary principle as applied to compressors, the disadvantages which developed have more than offset any advantages gained.

6. The rotary principle, however, is so valuable that, in spite of their deficiencies three general types of rotary compressors have been retained, namely, the centrifugal blower, the gear-type compressor, and the eccentric rotor with a telescopic blade. The centrifugal blower depends more upon the velocity of the air than upon compression and requires several stages to secure any considerable degree of compression. The gear-type compressor, in which there are two moving members, which, roughly speaking, compress air between two gears with their teeth in mesh, taking it in at one side of the teeth and delivering it at the other, has a very low efficiency, but is able to compress to a higher degree, single-stage, than either of the other types. None of them, however, compresses to over 8 or 10 lb. single-stage. There are many modifications and variations of these three types, but they represent the vast majority of rotary compressors.

7. Once again the mechanical world is about to be startled, perhaps, with a story of a perfected rotary compressor, or at least, it is hoped, interested. Since the writer is not the inventor and has a reputation to consider, it may be assumed that when he makes unqualified statement that it is possible with a rotary compressor to get commercially 92 per cent. volumetric efficiency at seven compressions, or 100 lb. per sq. in., that the compressor will, without adjustment or alteration, handle gas or a liquid, or a gas and liquid at the same time, close investigation has been made and the statement is based upon something more than paper facts. Until explained it will raise still further doubt when it is stated that the perfected high-pressure rotary compressor is built on the eccentric-rotor-and-telescopic-blade principle, this being the least efficient of the three types above referred to and the only one

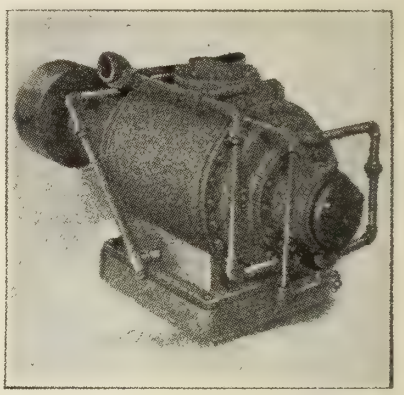

FIG. 2—TWENTY-TON ROTARY REFRIGERATING MACHINE.

that has had no commercial applications except in small water and oil pumps.

8 Before proceeding with the description of the perfected compressor let us analyze the troubles which have been experienced with this type of machine. The first and greatest was that it was necessary to maintain a seal at one point between the rotor and the cylinder. This was a source of large friction losses and the seal was soon broken by wear. Second, the blade pressure against the end plates and the inner surface of the cylinder created great friction loss and still further wore the cylinder at the contact point between the rotor and the cylinder wall. Third, the pressure being all on one side of the blade created such friction that the blade did not work in and out freely. Next, it was found impossible to devise a method of packing square corners, and hence the only commercial application of this type was in the pumping of oil or water at a comparatively high velocity, which service produced the least friction and no important losses.

9. The compressor about to be described was perfected by W. G. E. Rolaff, of the Research Engineering Company, St. Louis. It is not an invention but the result of long, patient research and the ingenious application of obvious principles. As stated, it is of the eccentric-rotor-and-telescopic-blade type, such as just described, except that the faults mentioned have been eliminated and the mentioned have been eliminated.

10. Taking the three difficulties enumerated in their order, the first men-

tioned, that of maintaining a seal at one point between the rotor and the cylinder, is fundamental. Some years ago a Mr. Hermansen developed an engine in which the cylinder revolved at the same peripheral speed as the rotor and was in fact carried by the rotor. Having both moving parts travelling at the same peripheral speed, not at the same angular speed, means that there is no slip between the two, and consequently little or no friction. It also reduces to a minimum the blade friction against the outside of the cylinder because the movement of the blade on the wall of the cylinder per compressive revolution is only that represented by the difference between the circumferences of the outside of the rotor and the inside of the cylinder. In other words, in a 100-cu.-ft. size, with a cylinder 10⅝ in. in diameter and a rotor 10 in. in diameter, the blade travel per compressive revolution is only the difference between 31.41 in. and 33.38 in., or less than 2 in., so that it requires approximately 17 revolutions of the rotor for one revolution of the blade upon the cylinder wall. In order that this may be brought out clearly the writer will state that there are no valve openings in the cylinder and that as it travels always in the same plane it makes no difference whether the cylinder is revolving with the rotor, standing still, or reversing itself, as far as compression is concerned. Hermansen's principle, however, solves but one of the many difficulties and by itself is valueless. Mr. Rolaff was unaware of this patent when he started his research work, and even after he had evolved the principle he did not think it patentable, due to its similarity to a roller-bearing detail. Hermansen had had no difficulty in doing so, however, and Mr. Rolaff was obliged to acquire the Hermansen patent.

11. The second difficulty, that of excessive end pressure, was overcome by floating plates at the ends of the cylinder held in intimate contact with it and the rotor by pressure generated by the machine itself. The pressure upon the outer surface of the plates is greater than upon the inner surface by reason of the difference in the area exposed to this pressure. This supplemental pressure is always in direct proportion to the pressure generated by the machine, hence the additional friction is only what is necessary to keep the cylinder heads in close contact with the rotor and cylinder ends; and it is obvious that where the pressure is even slightly greater on the outside than on the inside there can be no leakage.

12. It will be seen that any motion imparted to the rotor shaft will immediately be communicated to the cylinder by reason of the metal-to-metal contact between the two. In other words, if the rotor is revolved the cylinder will revolve with it and the cylinder plates will float with the cylinder or piston or between the two as the case may be. The friction developed is merely the friction of the wiping contact between the rotor ends and the cylinder plates, since there is very little or no friction in the rolling contact between the rotor and the cylinder.

13. There still remained the question of packing square corners and of friction between the ends of the blades and the end plates. When the rotor is revolved the piston blades which fit loosely in the slot fly out by centrifugal force and remain in contact with the cylinder wall and the cylinder heads, since centrifugal force acting on a wedge keeps them in such contact.

14. It has already been stated that the cylinder revolves with the rotor. Since the piston blades also revolve with the rotor and at approximately the same speed as the cylinder, it follows that the piston blades create very little or no friction on the inner wall of the cylinder. This is also true of the cylinder heads, hence the friction at this point is negligible. At each revolution of the rotor the piston blades travel in the slot to the extreme limit of the crescent-shaped displacement space and back, and in such travel they rub back and forth against the cylinder heads. This is the principal point of friction. But calculating this friction on basis of speed in feet per minute, we find, for instance, that on a machine capable of compressing 100 cu. ft. of free air per min. the piston-blade travel is approximately ⅝ in., and since a machine of this type would run at about 900 r.p.m., we have the following calculation: ⅝ in. × 2 × 900, which gives 93 ft., and since the surface in contact with the cylinder heads is very small, the total amount of friction generated by this reciprocating action of the piston blade is proportionately small:

15. These blades as developed are of two types, centrifugal and pressure. At present the centrifugal type shown in Fig. 1 is used commercially. This blade consists of four parts, one of which, A, might be termed a blade in itself. Part of this is cut away as shown, and on it are imposed three thin blades, B and C, of any desired metal. It will be noted that the two outside pieces B are beveled and that the centre piece C fits between these, forming a wedge, and that the top of C is cut away to allow of movement vertically. Revolving at speed the centre piece C is thrown out by centrifugal action, the force exerted on each piece B being in the direction of the arrow. This presses the B pieces against the sides and ends of the cylinder. These blades are self-aligning and self-adjusting, also self-compensating. The force with which these blades B strike against the corners is regulated

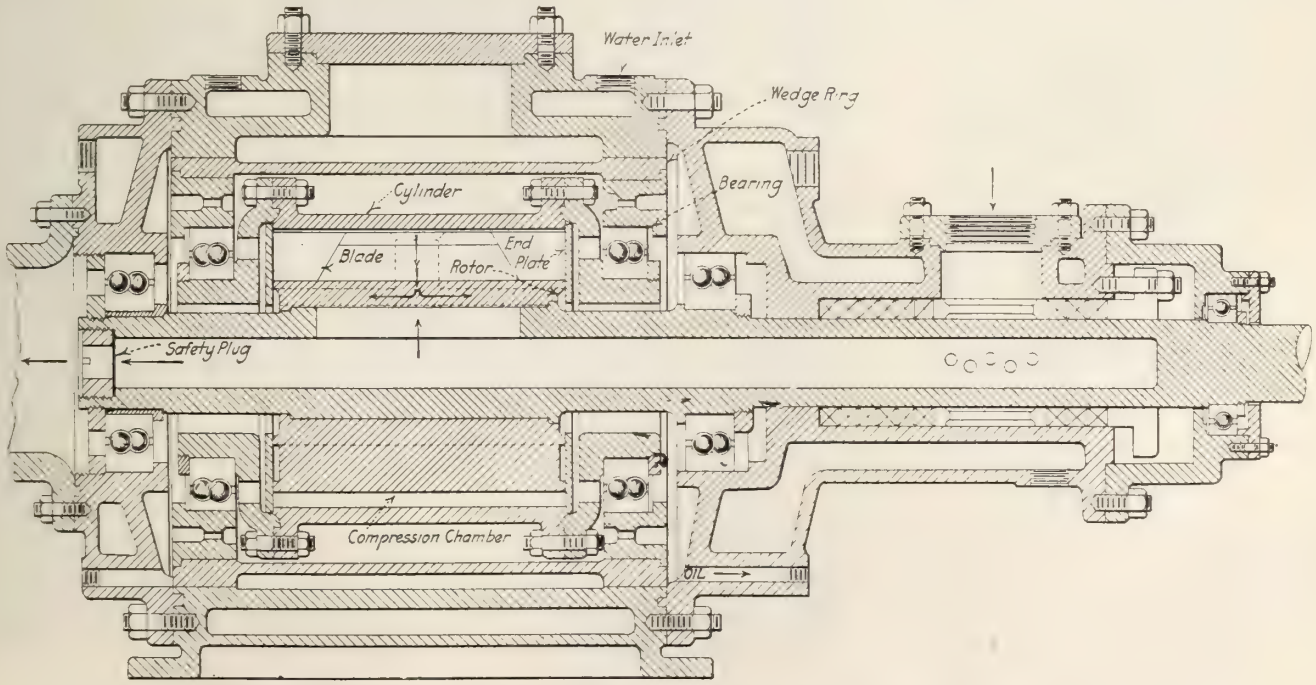

FIG. 3—CROSS-SECTION ASSEMBLY OF 20-TON REFRIGERATION MACHINE SHOWN IN FIG. 2.

by the angle of their inner sides and the weight of the centre piece. There are no springs whatever and the blade is balanced for back pressure by having both sides exposed to chamber pressure with a seat at the top of the slot in back, and as oil from the cylinder wall is scraped off by the blade into the slot, an effective seal is maintained. The blade A is about 1-32 in. short on each end and makes contact with the cylinder wall except at the extreme corner and side. The discharge valve is immediately in front of this blade. Fig. 2 is reproduced from a photograph of a 20-ton rotary refrigerating machine of the type under consideration, a cross-section assembly of which is shown in Fig. 3.

16. One of the greatest advantages of the compressor is that it may be direct-connected. It can be run at any speed at which a prime mover can be run safely. A 100-ton refrigerating machine is run at 600 r.p.m., a 1-ton or 5-cu.-ft. size at 1800 r.p.m. The first thought of a mechanical engineer at this statement is that the piston speed is entirely toto high for efficiency. Let us take from a catalogue the data on a reciprocating compressor of 14 in. stroke and having 100 cu. ft. capacity at 200 r.p.m. The piston speed would be 466 ft. per min., or over 200 per cent. in excess of a rotary compressor of the same capacity run at 900 r.p.m., with a relative speed of 150 ft. per min. between the rotor and cylinder. The next advantage is in its space requirements. A 100-ton rotary compressor on its base with its prime mover requires only 60 sq. ft. of floor space, whereas a horizontal reciprocating unit of the same capacity requires approximately 1200 sq. ft. plus a building, plus a boiler room, and weighs 100 lb. per ton capacity as against approximately 8 lb. for the rotary. It is usually possible to replace any pump or compressor with a machine weighing less than the flywheel of the displaced unit. With engineers the prime consideration is always efficiency. With the high-pressure rotary compressor, as before stated, the volumetric efficiency at 100 lb. pressure is 90 to 92 per cent., depending on size, as against 65 to 85 per cent. with the reciprocating machine. A number of engineers who tested one of these machines were nonplussed by finding that at no discharge pressure it had a volumetric efficiency of 107 per cent. Never having encountered this phenomenon before they were at a loss to know whether the capacity as given by the company, the instruments furnished by it, or their own instruments or arithmetic was wrong, and for seevral days they did not give out any conclusions. The manufacturer was of course familiar with it and suspected what their troubles were as such action is not uncommon in uniflow machines, but the best information obtainable is to the effect that the greatest volumetric efficiency found is usually about 102 or 103 per cent.

17. It has been stated that these compressors without adjustment or alteration would pump gas, air or liquid, or all three. Those who have had experience with refrigerating machines know that when ammonia condenses in the refrigerating coils and a "slug," as it is called, happens to get into the compressor, usually a valve or a cylinder head is blown off. One of the tests of the rotary compressor, for the benefit of visitors, is the pouring of a 5-gal. tank of oil into a compressor running at full speed under load, as fast as the inlet pipe will take it. The secret of its ability to take care of this is simple. Since the end plates are held to the cylinder only by differential pressure, if when the oil enters the cylinder and cannot be discharged fast enough by the valves, the end plates open up, allow the oil to pass out and then close. It is obvious that when pumping fluid continuously the pressures inside and out would again be different and be relatively maintained, so that no leakage would occur. In other words, the loose end plates act as safety valves without effort, as any necessary area of exit is secured and the oil leaves the cylinder at just sufficient pressure to raise the end plates. This feature is valuable in pumping hot water, or gas and oil.

18. Another feature of this construction which as yet has not been dealt with is the possibility of making the compressor double-acting by placing two blades 180 deg. apart, which would add from 60 to 70 per cent to the capacity of the machine. Until recently, however, no effort has been made to do this as it requires an intake valve, which is troublesome. In the simple type no intake valve is used, the seal between the rotor and cylinder acting as such. The major trouble with all air compressors, reciprocating or otherwise, lies in the valves, and the same trouble was found initially in the rotary compressor. It was aggravated somewhat in the rotary by the fact that cracking or splitting of the valve in its cage was not immediately perceptible, and it was possible for a valve to gradually break up into fine pieces and get into the cylinder. Experiments were undertaken to find a suitable material, and this has been done for cases where the temperatures do not exceed 200 deg. Fahr. In the 100-ton size the discharge valve is about 24 in. long by ½ in. wide, so it will be seen that the problem differs from that of the reciprocating machine.

19. The next and most important things to consider are the commercial uses of the rotary compressor. Broadly speaking, it may be said that these embrace every one possible to a compressor of the reciprocating type and some that are not. It is possible to get 500 lb. pressure single-stage; to get 1,,000 lb. pressure in three stages with the three units on the same shaft; to make it a low-pressure machine, giving it any desired capacity by making the rotor relatively small, and to give even more than 1,000 lb. pressure single-stage by reducing the displacement. As a vacuum pump it will pull 28½ in. against a pressure of 180 lb., but to do this continuously with a compressor it is necessary to shut off the oil pipe, and for commercial practice it would be necessary to have a self-contained oiling system. These high single-stage pressures and vacua are of course interesting only as illustrating the possibilities of the rotary compressor as compared with the reciprocating type. It is of course not desirable to compress to 500 lb. without intercooling unless we wish to use the compressor as a Diesel engine, and to pump 28½ in. vacuum against 180 lb. pressure is unnecessary and merely demonstrates the excellence of the machine.

20. The firm handling the rotary compressor in question has already been asked to consider the making of blowing engines for blast furnaces, as compressors of the rotary type do not take up more than 5 per cent. of the room now necessary. These rotary compressors are in use at the present time as boosters on refrigerating units for both high and low pressures. One of the large packers has four. The small household refrigerating business has not grown because it has been found impossible to secure a dependable compressor. One manufacturer is at present building units using this rotary compressor. It is a 0.5-cu.-ft. size, runs at 1760 r.p.m., is direct-connected, and is perceptibly noiseless (practically noiseless means nothing, absolutely noiseless means too much, so "perceptibly" is used advisedly), as are all other sizes of this compressor. The rotor in this size is 1⅞ in. in diameter and 1 in. long. Another manufacturer is making the 3-ton refrigerating size. Still another has a contract on which is guaranteed a minimum of 10,000 cu. ft. per year for street car compressors. Its use for this purpose should be extensive, as no satisfactory reciprocating pump has ever been designed. Another use is as a small individual unit for refrigerating cars, run either from the axle direct or with a motor from a turbine in the engine. Upon arrival at terminals, instead of the expense and waste of icing, it will only be necessary to plug in. Dining cars are still another use to which, among a multitude of others, it may be put. Imagine a cooled Pullman compartment on a hot, dusty day!

21. Used as an air compressor the rotary compressor is ideal, as the air is taken off at the centre and the oil thrown out centrifugally to the periphery.

22. No rotary pump is at present made that will prime itself, but this is not true of the compressor when used as a pump. Further, so far as the writer is aware, no reciprocating pump manufactured handles CO_2 successfully for any length of time. Those that do so at all are usually packed with leather, which wears rapidly. Because of the high efficiency and the character of its cylinder construction there would seem to be little doubt of the rotary's ability to handle CO_2 continuously without repairs. This, however, is in the future, which also applies to hydraulic applications.

23. The compressor may be built either vertical or horizontal and in the small sizes up to 5 cu. ft. it is air-cooled. Between this and the 15-cu.-ft. size it is partly water-cooled. In the 20-cu.-ft. size and above it is completely jacketed.

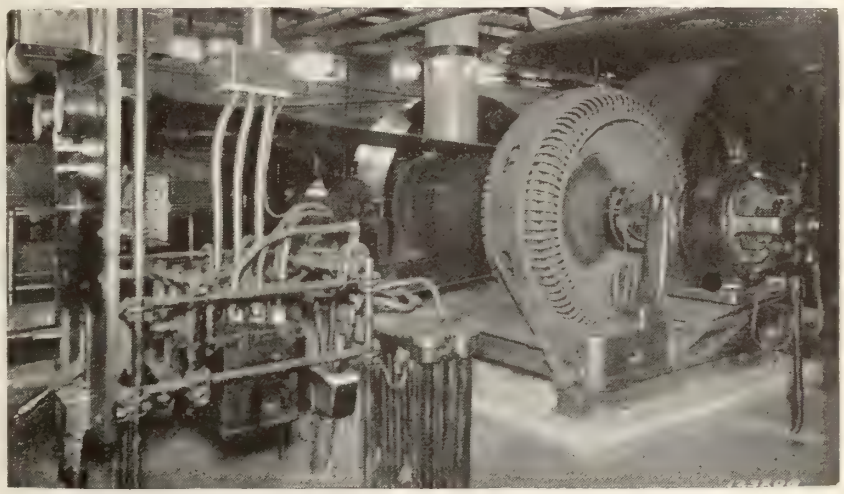
The Synchronous Motor and Refrigeration

Despite the Apparent Advantages of the Induction Motor for Many Uses the Synchronous Machine is Rapidly Ousting Its Rival in Many Fields—Its Use in the Refrigeration Plant is Here Described

By WILLIAM H. EASTON

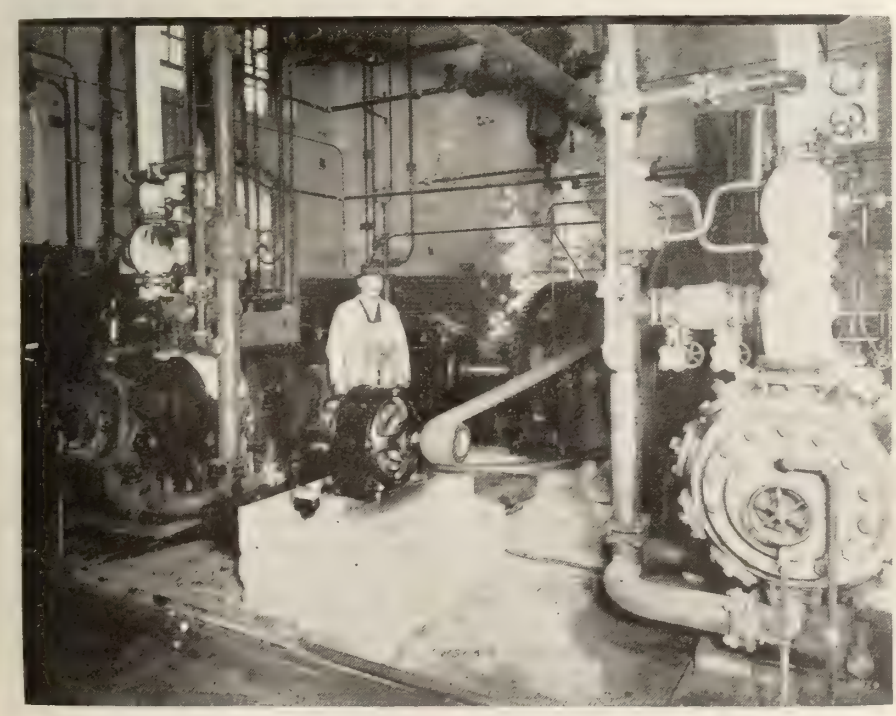
It is difficult to discuss the subject of power factor in a few words, but briefly, low power factor means a loss of power. When the power factor of a circuit is 80 per cent., only about 80 per cent. of the current flowing through it is available for producing power; the remainder circulates idly, requiring coal to produce it and copper to carry it, but unable to do useful work. Hence with an 80 per cent. power factor, the generator, transmission lines, transformers, and other apparatus must be 25 per cent. larger than would be necessary to handle the same amount of power at a power factor of 100 per cent. Other disadvantages, such as poorer voltage regulation, are also caused by low power factor. H. P. Under the best of circumstances the power factor of an induction motor is not much over 90 per cent., while for very low speed machines, such as would be necessary for direct connection to refrigerating compressors, the power factor is even lower. The synchronous motor, however, not only operates at 100 per cent. power factor itself, but also can be arranged so as to connect the lowering of the power factor by induction motors operating on the same circuit.

The use of the synchronous motor by an industrial plant is therefore advantageous because it provides current of the most desirable characteristics and permits the use of smaller transformers and other apparatus. To the central station the maintenance of high power everywhere on its lines is of great importance, because the idle currents that appear with low power factor are a source of expense but create no revenue. Hence central stations encourage the use of synchronous motors wherever they can be properly used.



500 H.P. SYNCHRONOUS MOTOR, 440 VOLT, 60 CYCLE, 350 REV. PER MIN., BELTED TO REFRIGERATING EQUIPMENT.

On account of its limitations of more complex construction, higher first cost, low starting torque, and unchangeable speed, the synchronous motor can not be used for a large variety of applications, but compressor drive is work that is well suited to it. Starting under full load is avoided by by-passing the compressor until full speed is attained and then throwing on the load. Reduced capacity in cold weather is obtained by driving two compressors by each motor, as in the installation illustrated, and using both in summer and only one in winter, instead of reducing the speed of the outfit. The more complicated construction of the synchronous motor is not an actual drawback, since the modern synchronous motor is quite as reliable, as easily operated and as readily repaired as the induction motor. Though its first cost is somewhat higher than that of an induction motor of the same capacity, the synchronous motor is somewhat more efficient and will save the difference in price in a short time by lowering the power bills.



Two 15 x 15 Vilta Compressors driven by a 350 H.P. direct connected synchronous motor: belted 13 1-2 k.w., 125 volt exciter.

Hence the synchronous motor is in every respect as satisfactory as the induction motor for driving refrigerating compressors. while its ability to maintain a 100 per cent. power factor makes it superior. So generally has this fact become recognized, that as a matter of fact, electrical manufacturers do not supply induction motors in the proper sizes and speeds for direct connection to refrigerating machines but offer synchronous motors only.

The Switchboard

The switchboard for controlling the equipment shown in Fig. No. 1 is simple, each of the three left hand panels controls a single motor-driven unit and carries the following equipment; a power factor meter and an ammeter; a motor field-switch; a motor-field rheostat and at the bottom, a starting switch for the motor which is so arranged that the motor can not be started

Boiler-Feed Water and the Formation of Scale

The Following Article, Reprinted Through the Courtesy of "Ice and Refrigeration," Was Delivered in the Form of an Address Before the Annual Convention of the National Association of Practical Refrigerating Engineers in Kansas City, Mo.

By W. A. CONVERSE

THE subject of boiler feed water is not as simple as the name might imply. Water itself, as obtained from its natural sources, is much more complicated in its character and action than many persons realize, more particularly those who have not had an opportunity of noting its action, both from a technical and a practical point of view. To thoroughly consider and understand any particular subject, it is necessary to have a general idea of the fundamentals underlying it; hence, if we are to consider the subject, "Boiler Feed Water," we must have at least some knowledge of what water really is, where it obtains its impurities, what they consist of, and in a general way, their influence as a part of the impurities contained in the water itself.

Water, to the technical man, is water in an absolutely pure state, devoid of all foreign substances, either gaseous, liquid or solid. Chemically, water is made up of two gases: Hydrogen and oxygen.

Hydrogen gas when pure is odorless, colorless, tasteless and non-poisonous. It has, however, the property of inflammability. If we should pass hydrogen gas through an ordinary gas jet and light it, it would burn in the same manner as does illuminating gas.

Oxygen gas has the identical properties of hydrogen, with one exception, i.e., it is entirely devoid of the property of inflammability. It will not burn, but it is absolutely essential to all processes of combustion. If it were not for this fact and the fact that a large part of the atmosphere which you allow to pass into the furnaces under your boilers, is made up of oxygen, you would not be able to obtain any efficiency therefrom, because there would be absolutely no combustion of the fuel.

If we should mix two quarts of hydrogen gas and one quart of oxygen gas, we would have a mechanical mixture of the two, in the proper relative amounts necessary to form water, if chemically combined. Thus far we have but a mechanical mixture and not a chemical combination of the two gases. Now, if we should produce an electric spark in the mixture, the gases would immediately enter into chemical combination and we would have formed a few drops of water.

Surface Water

For our purpose at this time we may assume that water has its origin at the surfaces of the seas, rivers, lakes, and last, but not least, from the surface of the earth itself. The action of the sun's rays upon these surfaces causes the evaporation of more or less of the water, which rises in an invisible form known to us all as humidity. Eventually it assumes the form of clouds, in which condition it becomes visible. The water composing the clouds may be considered as being in a pure condition because of the fact that it has passed through a natural process of distillation. The water exists in clouds in a very finely divided condition, i.e., divided into very minute particles which are so small that they remain suspended in the air. Due to atmospheric temperature changes, electrolytic disturbances, or both, these extremely minute particles combine, one with another, and form larger particles which readily fall to the surface of the earth. Water falls to the earth in several different forms, as rain, snow, frost, dew, etc. However, we shall consider it only as falling in the form of rain.

Immediately following the beginning of the fall of water from the clouds in the form of rain, contamination begins. Air is a mixture of gaseous elements present small amounts of carbonic acid, element retaining its own characteristic properties. Aside from the two principal gases composing the atmosphere, viz., oxygen and nitrogen, there are also presetn small amounts of carbonic acid, nitric acid, and ammonia; and, in localities where bituminous coal is the chief fuel, and particularly where this fuel is heavily impregnated with sulphur, the sulphur, in the process of combustion, is converted into sulphur gases which impregnate the air and, along with other constituent gases, are taken up by the water—the sulphur gases eventually becoming converted into sulphuric acid.

Earth Substances Taken Up

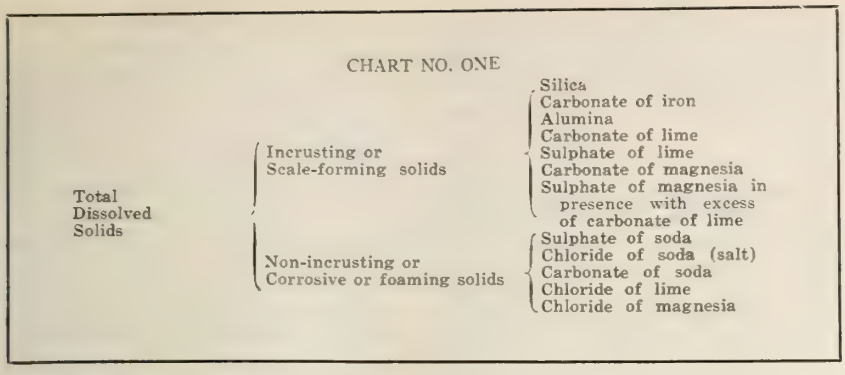
Assuming, now that the water has passed down through the atmosphere and has reached the immediate surface of the earth, it has taken up some carbon dioxide (CO.), some ammonia undoubtedly, some sulphur gases, and probably some oxygen (since the air is made up, to the extent of twenty per cent. of this gas)—all of these gases being in solution in the water itself.

What happens at the immediate surface of the earth? That depends upon the litter or refuse which covers the surface of the earth upon which the water falls. If the surface is strewn with decaying or rotting vegetable matter, such as timber, leaves, twigs, etc., it takes upon another portion of carbon dioxide (CO_2) because the process of rotting of timber for instance, is nothing more or less than a slow process of combustion, identical in character in every chemical respect with that which takes place underneath your boilers; that is, a combining of the oxygen of the atmosphere with the carbon of the fuel which you are burning, or the carbon forming the greater part of the vegetable matter which is in process of decay. The only reason you do not notice heat or light in the case of the decaying of vegetable matter is because the rate at which the oxygen of the atmosphere combines with the carbon of the decaying timber is not sufficiently rapidly. If the combination in the process of decay were going on as rapidly as it is in your furnace, you would perceive temperament and light as well. If the water falls upon a surface strewn with animal matter like we have in the stockyards district in Chicago, where there is more or less animal matter which is converted into ammonia compounds, it takes up more ammonia at this point. Then, again, animal fats like tallow and lard, are made up in part of fatty acids, and these fatty acids are rather soluble in water, and are readily taken up in moderate quantities by water coming in contact with them, and are extremely destructive to metallic surfaces. These are only a few of the substances that are commonly taken up just at the surface of the earth.

And having reached the surface of the earth, the water either permeates the earth itself or travels through channels such as river beds, etc., to the sea. In either case the water coming in contact with the various substances composing the earth dissolves or takes up varying quantities of these substances. In other words, where the strata with which it comes in contact is largely composed of limestone (native carbonate of lime), carbonate of lime will predominate in the water; in case of gypsum (native sulphate of lime), sulphate of lime will predominate; and similar are the results with most all other solid substances contained in natural waters.

I have prepared and here present a chart which shows the substance usually found in natural waters. I am barring from consideration at present, suspended matter and some substances which may be considered later if time will permit. This chart shows all the substances which are found in practically all waters, those containing other substances being by far the exception:

CHART NO. ONE



You will notice that the substances on the chart are divided into two classes; incrusting or scale-forming solids, and non-incrusting or corrosive and foaming solids. This means that all those substances shown under the former classification can and do enter into scale-formation, these substances being the silica, carbonates of lime and magnesia, sulphate of lime, and sulphate of magnesia when present with an excess of carbonate of lime. Those coming under the latter classification, due to their extreme solubility, can not and do not enter into scale-formation; namely, sulphate of soda (Glauber's salts), chloride of soda (common salt), and carbonate of soda (soda ash). On the other hand however, when present in a water in relatively large quantities, they do give rise to foaming, corrosion and many other types of troubles.

Since the carbonate of lime and the carbonate of magnesia (more particularly the former) are readily, largely precipitated or thrown out of solution at a temperature of 212 degrees fahr. or less, you can understand why you have an accumulation of a soft carbonate of lime scale in your heaters, and frequently this extends into the feed lines and pumps, sufficiently, in many cases, to necessitate cleaning or putting in new feed lines, shutting down pumps to clean valves, etc. In no case does such a water enter the boilers sufficiently devoid of these substances to obviate the formation of scale.

Aside from the formation of some scale in the boilers, waters of the type under consideration give rise to the accumulation of much mud due to further precipitation of the carbonates of lime and magnesia in the boilers and the carrying mechanically, with the water, of a part of the substances previously precipitated in the heater. The carbonate composing the mud remain, for some time, in a very light and fine condition, in fact, so much so that much of the precipitated matter floats upon the surface of the water in the boiler while in action. Due to the bursting of the steam bubbles at the surface of the water, the steam space becomes thoroughly permeated with the particles, which are, in turn, carried over, mechanically, with the steam; and, in cases of reciprocating engines, the mud becomes mixed with the cylinder oil on the inner surfaces of the cylinders, which (due to continued rubbing together), assumes the condition of putty. In the case of turbine engines, this results in the formation of a deposit upon the surfaces of the vanes of the turbine, necessitating closing down the turbine for cleaning, which means delay and expense.

Previously, we have been considering the action of a water wherein na part of the scale-forming substances consisted of sulphate of lime. If, now, this same water contained a quantity of sulphate of lime equivalent to 25 per cent. of the total incrusting solids, the results in the boiler would be entirely different. The temperature to which the water is heated in the boiler results in the precipation of the sulphate of lime, which means the accumulation of a greatly increased amount of scale of very much greater hardness and tenacity. The sulphate of lime, following its precipitation by mechanical action, causes the small particles of precipated carbonate of lime to settle rather than to remain on the surface of the water, thereby obviating the troubles heretofore cited in the cylinders of reprocating and turbine engines.

Passing, now, to the consideration of the second or the non-incrusting group as shown by chart: As previously cited, these substances, due to their extreme solubility in both hot or cold water, can not and never do enter into scale-formation, proper. On the other hand, they give rise to trouble in the form of foaming, corrosion, oozing out at and causing leaky joints, leaky gaskets, etc.

Assuming, now, that we have a water wherein the second group of substances constitutes 50 to 60 per cent. of the total solid matter—if the solid matter present amounts to 50 grains per U. S. gallon or more, and the water is being used in boilers worked appreciably beyond their rating, or boilers which are submitted to very uneven load at times, foaming would be the result, which would increase in intensity from hour to hour. In case of a water containing, say, 14 grains of total solids, of which 7 grains consisted of substances of the second group, foaming would not take place before the lapse of a greater length of time following the putting of the boilers back on the line after washing, but would eventually do so, as, in a short time, the water in the boiler would reach a saturation corresponding to that of a water which would foam at the outset. For example: A 500 h.p. boiler, being operated 24 hours per day, would evaporate approximately 45,000 gallons of water. Since 7 grain per gallon is equivalent to one pound per each thousand gallons, there would enter the boiler during each day's operation 45 pounds of these soluble salts. If, then, the boiler is kept on the line for 15 days, there would enter the boiler 675 pounds of said foaming salts—all being in solution in the water in the boiler, which would be more than sufficient to cause much foaming.

Acid Waters

While it is not general, it is not uncommon to find waters containing substances not mentioned on the chart, more particularly those containing free or uncombined acids—sulphuric acid being most commonly encountered. Sulphuric acid is generally found in surface waters in districts where mining or smelting is done on an extensive scale, as you know that, in such districts, there exists varying quantities of ore and waste materials, all of which contain rather large amounts of sulphur. The sulphur, due to action of moisture and atmosphere, becomes converted into sulphuric acid. The district in and about Pittsburgh, Pa., constitutes a very good example. I am informed that, some years since, a certain bureau of the Government estimated (following a careful survey) that there entered the streams of this district, approximately 600 tons of this acid daily. Since most metals, more particularly iron and steel, are soluble in moderately weak solutions of sulphuric acid, you can readily appreciate the rapid destructive effect of water containing it would have upon the interior surfaces of pumps, boilers, etc. The visible effect is that of very rapid corrosion of the surfaces with which it comes in contact. Furthermore, this acid is not volatile; consequently, all that enters the boiler with the feed water remains therein, increasing in quantity in the same manner as the foaming salts previously referred to, so that, even though the feed water contained but a small amount, the water in the boiler would be so heavily impregnated as to constitute a strong solution.

Water Treatment

The treatment of waters, generally, may be conveniently divided into two classes, known as external and internal—the former commonly known as "water softening."

The external class includes all methods of softening of the water before it enters the boilers, and has the effect of reducing only the amount of scale-forming substances, as all other ill effects of a water in a boiler are in no way eliminated or reduced, but, on the other hand, are increased.

The internal class consists of methods of treatment of the water in the boiler while in operation, usually by injection of the treatment into the feed water as it is going to the boiler.

Representative of the external class, the most important method is known as the Porter-Clark, or the lime and soda-ash method. This method was brought forth about 1850, at which time it was a long step forward as compared with what had previously been done. It was rather expected that, by the use of this method all boiler troubles would be solved, but, as a matter of fact, such was not the case, even so far as concerned the elimination of troubles confined to the action of scale-forming substance—while other effects or actions (ofttimes serious) were created.

Any water, even the softest possible to obtain, by the application of lime and soda-ash or caustic soda (per the outside method), still contains and carries into the boiler with it, approximately 4 grains of scale-forming solids per U. S. gallon—said 4 grains per gallon being equivalent to .571 lb. per 1,000 gallons. A 500 h.p. boiler operating 24 hours per day, would evaporate (in round figures) 45,000 gallons, which would result in carrying into the boiler 25.7 pounds of incrusting solids, which, in fifteen days' run between washouts, would amount to better than 385 pounds. It is true that all of these incrusting solids do not enter into formation, but a sufficient amount does, so as to demand further treatment in the boiler if the latter is to be kept free from scale. On the other hand, a considerable part of these incrusting solids are thrown out of solution in the boiler in such a finely divided and light condition that they float upon the surface of the water, and are thrown into the steam space, from where they are carried mechanically with the steam, later on giving rise to deposits of puttylike consistency in cylinders of reciprocating engines, and deposits on the vanes of turbine engines, frequently making it necessary to take the engines out of service, open and clean.

The use of the soda-ash (or other soda salt) in the outside treatment is for the purpose of removing from the water any sulphate of lime contained therein. It does this perfectly, if used in proper quantity and if sufficient time is allowed for the necessary reactions to take place. Since, however (due to these reactions) there is left in the softened water a quantity of sulphate of soda corresponding to the amount of sulphate of lime removed, and the sulphate of soda gives rise to tendency to foaming in any case, and to actual and serious foaming in many cases, the tendencies of carrying over of mud from the boiler are very much increased.

Experience has brought the speaker to the conclusion that, where a water is a sufficiently hard, scale-forming one to justify the purchase and installation of a plant for the application of this method in at least seventy-five per cent. of the cases, other troubles such as foaming, corrosion, oozing out at the joints, destruction of gaskets, etc., are created to such an extent as to make it necessary to further treat the softened water with a suitable preparation to be applied by injection into the boiler with the feed water.

The next in prominence and much more recent method for outside softening of water, is one known as the "Permutit" method. It consists of passing the water through an artificial zeolite to which the name "Permutit" was given by the discoverer, Dr. Gans, of Berlin. Without going into detail as to the chemical composition of Permutit contained in a specially devised apparatus, the hardness of the water is reduced to nil. Since, however, the hardness of water is due exclusively to the scale-forming salts, such a reduction of hardness indicates only the removal of same, but indicates in no way what else has happened. The facts are, that, while the scale-forming salts have been practically eliminated, the softened water, in practically all cases, contains a decidedly increased amount of solid matter. It must then follow, of necessity, that since the scale-forming salts have been removed, they must have been more than replaced with other substances—which is the case.

Usually, the replacement substance is principally carbonate of soda (soda ash); in fact, most waters treated by this method, contain such quantities of carbonate of soda as to prove more objectionable, so far as foaming and similar troubles are concerned, than waters softened by the lime and soda-ash method. Pre-treatment of the water with lime has been resorted to, in some cases, for the prevention of the great accumulation of carbonate of soda in a water after being permuted. Again, however, it seems generally necessary to follow this method of softening with the use of a suitable internal treatment, either to overcome foaming or to prevent corrosion due to the use of too pure water.

Along with the consideration of methods of apparent merit, such persons as have been specializing in certain lines frequently come in contact with proposed methods for accomplishing certain results, which are amusing in the extreme. At this time, one of such methods comes to mind, and I feel that it might prove of interest to you for its peculiarities. The apparatus consisted of sets of corrugated aluminum plates about twelve inches wide and of various lengths, placed at an angle of eighty degrees under a V-shape trough, the latter being perforated at the bottom in such a manner as to cause the water passing from the trough to do so in small streams, each stream falling into the depressed portion of the corrugated plates; then running down over the aluminum plate to storage tank below. No chemicals were to be used, but, in order that the desired results can be obtained, the apparatus must be set so that the plates should face precisely north or south in order that objectionable substances contained in the water would be exposed to the action of galvanic, electric, or some other imaginary currents passing between the north and south poles of the earth.

I feel that it might be interesting for you to know that, despite the mysteriousness of the method, and despite the fact that samples of water of various qualities were taken before passing and after passing through the softened, and were analyzed with absolutely no change being detected—some of our largest water users (most of whom, by the way, were maintaining laboratories in charge of competent chemists) were prevailed upon by smooth-tongued salesmen to install the apparatus. Of course, the matter was not submitted to their chemists for an opinion.

Internal Treatment

As you would naturally infer, the internal method of treatment would consist of the treatment of the water after it enters the boiler, and if satisfactory results are to be expected, the treatment constitutes the use of chemical or chemicals in the form of so-called boiler compounds. It has been shown that waters, even after having been submitted to some outside water-softening method, demand the further use of a suitable compound for the purpose of finishing the job, or, in other words to do what the softening process could not do, i.e., to overcome trouble in the form of foaming, corrosion, etc., due to the new condition of the water itself, brought about due to the method of softening.

This being true, it seems that most waters can be more economically and more successfully treated by the internal method. There are, however, cases where it is advisable to resort to the use of a combination of the two methods, i.e., where a water is so hard a scale-forming one as to make it an impossibility for internal treatment to first remove, at least, the greater part of the scale-forming substances by outside softening, this is to be followed with the use of a suitable preparation to bring about satisfactory conditions. Just at this time, I desire to impress upon you the fact that the outside methods bring about absolutely no improvement in a water other than reduction of the quantities of scale-producing substances, and such improvement is, as previously cited, generally counterbalanced by induced and increased tendencies to foaming, etc.

Since the successful internal treatment of the water is necessarily a chemical one, and different substances are necessary to react chemically the various substances contained in the feed water, it necessarily follows that, in order to insure results, an analysis of the water must be at hand, and from this the selection made of such chemicals as will react with each of the substances contained in the water, and the various amounts necessary to incorporate in the treatment or compound determined, and from these results the treatment built up.

Again, in view of the fact that the deleterious effects of a boiler water are, at least, equally dependent upon the relative amounts of the substances present as to the total quantity, the absolute

necessity of an analysis of the water to be treated becomes apparent.

The speaker has known of many cases where a compound was furnished with a guarantee on the part of the seller, which consisted to the extent of 85 per cent. of the particular substances present in the feed water which was directly responsible for the action which was to be overcome. Such sale and guarantee would, undoubtedly, not have been made if the seller had had an analysis of the water, especially had the seller desired to actually overcome the trouble.

From the foregoing, I feel that you can readily appreciate that an analysis of the feed water to be treated must be the first step to be taken, this accompanied with a thorough knowledge of the conditions governing the boilers in operation, followed with the construction of formula and, finally, the putting together of a correct and suitable, scientific treatment—will insure the best possible and most economic results.

Time is not at hand to permit of entering, to any great extent, into a discussion of this phase of the subject, but the matter of corrosion in steam boilers to-day is demanding more consideration than ever before. I believe that I am fairly correct in saying that 50 per cent. of the demand for treatment, for use more particularly in stationary boilers, is either wholly or in part for the prevention of corrosion.

Three principal theories have been advanced in the past, covering the subject of corrosion, viz., the carbonic theory, the peroxide theory, and the electrolytic theory. Since the advancement of the electrolytic theory, which has been generally accepted as the most rational one, the other two have been cast aside.

No doubt many of you at least have had the opportunity to look over a chemist's report covering a sample of iron or steel; in case you have you must have noticed that he did not state the amount of iron it contained, but he did tell you that it contained carbon, silicon, manganese, sulphur, phosphorous, etc. Each and every one of the substances, as they exist in the metal of the sheets or tubes, are chemically combined with a certain amount of the pure metallic iron or other metals, forming new substances characteristic of themselves, which are very different from the pure or uncombined iron itself. The balance of the metal is made up of uncombined iron commonly known as uniform composition, and knowing that practically no two different substances are soluble to the same extent, we can assume that the compounds of iron which were the most soluble in the water in contact with their surface would first of all dissolve to the greatest extent, which would result in the corrosion showing in the form of pitting rather than taking place to a uniform extent over the entire surface.

Aside from corrosion due to the presence in the feed water of actual corrosive substances, or those which contract the properties necessary to such an effect, due to hydrolization or decomposition thereof, we have another and equally objectionable condition possible—that due to electrolysis or galvanic action.

Science tells us that every substance in existence is either electro-negative or electro-positive to every other substance. We also know that it is not uncommon in boiler practice to have present a noticeable galvanic current, which, if this theory is correct, must result in corrosion. There are three essentials to a galvanic cell, namely an electro-positive, an electro-negative substance, or pole, and an electrolyte or carrier. We frequently have them even in a small area of sheet or flue, the necessary different substances to act as the two poles and the presence of a layer of water over the surface will act as the carrier. Therefore, we have the necessary elements of corrosion. If the water carries more or less common salt, or some other substances, the current-carrying capacity of the water is enhanced and the tendency to corrosion relatively increased.

You must not overlook the fact that practically all steam boilers in service are directly connected with or have attached to them various valves and fittings, and at times other metallic accessories, to say nothing of the difference in the character of many flues or tubes, or the flues or tubes and shell, or both, all of which tends to corrosion in some form.

You may have either wrought iron or steel flues or tubes in your boiler, which are absolutely of as good quality as possible to obtain, but at the same time, sufficiently different in their composition or homogeneity or both, to furnish a possible condition resulting in corrosion.

Since, as previously stated, there are three essentials to an electrolytic action, it stands to reason that if we can eliminate one of these the trouble will be overcome. It is not possible for us to prevent two substances acting in the capacity of the two poles of a battery, under favorable conditions, but it is possible to so change the water being used as a feed supply as to destroy its ability to act as an electrolyte, and thereby prevent corrosion.

In conclusion, I desire to say that, in my opinion, no boiler feed water problem is so small or so unimportant as to not demand an analysis of the water, and a careful study of the conditions governing the operation of the boilers—which should furnish definite information of the actual cause of the trouble. This, followed by a careful study of the various methods of treatment and the final results to be obtained should result in the best possible conditions. Since certain companies are including in their service to customers and prospective customers, the gratuitous analysis of waters, and assume an unbiased position, I feel that there is no excuse for those experiencing trouble in their boiler plant, who do not take advantage of such service. I thank you.

Members manifested a great interest in the paper by Mr. Converse, and there was an extended discussion on various points. Mr. Register raised the question as to how a plant operator is to regulate the treatment of his water when the condition of this water may vary almost from day to day. In reply, Mr. Converse stated that while it is true the actual amount of impurities in the water may vary considerably from time to time, a water supply from a given source will, as a rule, contain the same materials at all times. In the case of dry weather there will be less of these constituents in the water and when a flood comes along, the quantity will be increased. Thus it is merely a question of properly increasing or decreasing the amount of material used in treating the water, so that it will correspond to the impurities contained. Of course, the ideal way is to take samples from time to time, and have them analyzed so as to determine about what the amount of change may be.

A member asked the question as to the benefit to be derived from using graphite in the boilers, and Mr. Converse stated that graphite is the most negative substance, electrolytically speaking, that can be used in a boiler. Zinc is the most positive and carbon the most negative; and as graphite is practically pure carbon, when it is placed in contact with iron there is a great difference of electric potential, so that as soon as there is enough moisture impregnating the material along with other substances, which cause it to act as an electrode, there is a galvanic cell action which sets up a current instead of preventing the electric current. From this it would seem that zinc, which is the most positive material, electrolytically speaking, would be an ideal substance to prevent corrosion in boilers. Theoretically, the speaker stated, this is true, but as a matter of actual practice, there are numerous difficulties in using zinc for this purpose. Among these are the cost of zinc, the difficulty of keeping it in proper position, and a proper distance from the metal parts of the boiler, and the fact that as soon as corrosion begins, the zinc goes to pieces and altogether it is found impractical to maintain the zinc plates in proper condition and position to perform the necessary work. In marine work, especially, and in many parts of the country for stationary practice, zinc plates have been tried, but so far with little practical success, although more has been done in marine practice than elsewhere towards adopting this method of preventing corrosion.

As to the matter of using some material to put a coating on the inside of boilers in order to prevent scale adhering, Mr. Converse thought this impractical, as he felt that it is not possible, either chemically or mechanically, to so prepare the internal surface of a boiler that scale will not adhere.

An Accident Hazard

AMMONIA, while deadly enough in itself if let loose in the refrigeration plant, is usually not looked upon as much of an explosive. By itself or mixed with air in varying proportions it is harmless, but when varying amounts of oil vapor, hydrogen, etc., are mixed with it as in a refrigeration system explosions have been known to occur. An article in the present issue points out a number of accident hazards in the refrigeration plant which are not likely to occur to the operating engineer and is well worthy of careful study.

Explosions can also take place in a compression system itself without the presence of ammonia. This was shown in testing out a compressor under 250 lbs. air pressure when the oil separator exploded with great violence. The explanation advanced was that the superheated air, forced from the compressor into the oil separator, found an explosive mixture with the oil vapor.

Explosive accidents to absorption systems are also quite possible, many of those which have occurred having been simply due to overpressure. There is also another cause for explosions in this type of plant; the dissociation of ammonia and the liberation of hydrogen is quite possible and the gases from the purge line being almost highly inflammable probably consist chiefly of this gas.

The author concludes with the statement—"that explosive accidents are so few in number is due not so much to the care with which the plants are operated as to the fact that fortunately all of the necessary conditions are only infrequently at hand. Finally it is most essential that strict watch is kept on the whole system from end to end in all details, as the failure of even an apparently unimportant part has been found sufficient to cause general havoc and even fatality."

Development of Our Water Power

THE utilization of water-power in Canada is advancing even more rapidly than heretofore. During 1919, the installation of plants with a total of 64,400 h.p. was completed in various portions of the Dominion; the developments at present under construction or in process of installation aggregate over 370,000 h.p. Other projects definitely contemplated for the near future will add 750,000 h.p.

Among the more notable developments are the 200,000 Chippawa plant of the Ontario Hydro-Electric Power Commission, now under construction, to utilize the full head of Niagara power, and the impetus given by the Quebec Government to the conservation of water by storage. Much activity is also to be noted in the Maritime Provinces.

This rapid progress, which represents industrial growth of the most valuable character, should be encouraged, yet most carefully guided. In the United States, electrical installations have doubled every five years while, in Canada, the present hydro-electric installation is about ten times that of 1900. The present hydraulic installation in the Dominion is nearly 2,400,000 h.p. If we assume for this country only one-half the rate of increase recorded for the United States, a total of 4,800,000 h.p. would be developed in 10 years, and 9,600,000 h.p. in 20 years, if available.—"Conservation."

Assassinating Arithmetic

THE Technical School is recognized to-day as one of the wisest provisions a country can make for the education of its youth, yet at times some seeker after notoriety, or perhaps some well-meaning, if misguided, enthusiast, recommends some radical change in the public school curricula which would have the effect of undoing the good of the technical school and leaving the majority of the rising generation without a proper foundation for earning their livelihood.

One such has recently made a statement to the effect that arithmetic should be, perhaps not altogether eliminated, but rendered quite innocuous so far as the public school pupil is concerned. He would eliminate complex fractions, recurring decimals, trains meeting and passing each other, boats going up and down stream, and true discount. While highly pleasing to the youth of the land, and while allowing time for more diverting and entertain-

ing subjects such as sculpture, music and the higher aesthetic attainments, any curtailment of the mathematical subjects mentioned could only be looked upon with apprehension.

Rather should arithmetic, and that other somewhat prosaic subject, grammar, be extended, and made to occupy more of the student's time in the public school. The true function of education is to prepare a man for his life's work and to enable him to profit by the experience or literary genius of others, and when the first of these is lost sight of it avails nothing that he be able to play the fiddle or enjoy himself otherwise if he is unable to earn his daily bread.

As a preliminary to a machine shop apprenticeship or a course of study in any one of the branches of the engineering profession, mathematics is essential, and the more knowledge of this nature a boy can assimilate in the public school, often his only chance, the better equipped he will be for his further training.

After all, the public school, high school and university are only the beginning of a man's real education, and the earlier he stops school attendance the more essential it is that he be given the most necessary and immediately useful knowledge.

Free Heat and Light Found by Hopeful Scientist?

HEAT, light and power free in every household would seem to be in the realm of possibilities, if the method described by H. H. Platt, a mechanical engineer of Philadelphia in an address before the American Association for the Advancement of Science, is practicable. Mr. Platt insisted that sufficient energy could be extracted from the air by his process to heat houses. He urged the scientists to aid in developing this new source of fuel "so as to relieve coal-oppressed humanity."

The device suggested to utilize the energy contained in sunlight consists of a very thin sheet of metal perforated with many small holes, which are prepared in such a way that air molecules, bearing energy, will pass through it more easily in one direction than in the other.

According to the accepted theory, the pressure which air exerts on a given surface is the sum of the impacts on it of rapidly moving molecules. If these molecules can pass through a sheet of metal more readily in one direction than in the other the result would be a slightly unequal pressure and the sheet of metal would tend to move toward the side of least pressure.

By mounting a number of such "partly irreversible permeable membranes" on a shaft like paddles on a mill-wheel, Platt asserted, a compact and powerful engine could be produced. The paddle-wheel would turn, generating power through its axis and at the same time removing heat energy from the air passing through its leaves—a feature that would make it adaptable for use as a refrigerating machine.

Mr. Platt depicted the householder of the future possessing a cheap machine which will furnish light, heat and power, and produce cold air for cooling the house in summer. The operating cost would be nothing.

We are unable just yet to accept the idea of fulfilment of Mr. Platt's programme in toto. As a matter of fact, it is a little difficult to follow the rapidity with which the various benefits to humanity would follow. It seems plain that if heat is transferred from one place to another, there will be a rise in temperature at the destination of the thermal units, with a corresponding drop at the point of withdrawal, providing the process should prove 100 per cent. efficient. Thus will the Philadelphia scientist obtain the advantage of refrigeration where it is needed, while supplying warmth so welcome to the oppressed rent-payer, at the same time, to say nothing of the light that the anti-daylight-savers deny us.

Someone has said that "rubbish is only matter out of place." Apparently this invention bids fair, in theory at least, to clean up a good deal of the uneconomical distribution of heat units in the world.—"Compressed Air."

Are You Wasting Coal or Conserving It?

WITHOUT accurate knowledge of how many pounds of steam you get per ton of coal consumed, you cannot know whether you are wasting coal or conserving it.

Here are a few questions which every manufacturer should be in a position to answer:

1. How many pounds of water per pound of coal are you evaporating?
2. Which of your boilers needs cleaning and repairing?
3. At what percentage of rating are your boilers most efficient?
4. Are you keeping your boilers at this point?
5. Of all the boilers in your plant, which have the greatest steaming capacity? (It is a well-known fact that all boilers, built in the same manner and apparently operated under similar conditions will not have the same steaming characteristics.)
6. What is the total amount of steam used in the engine room?
7. What is the amount used by each unit?
8. What is the total amount of steam used for manufacturing purposes?
9. What is the amount used by each department?
10. How much steam are you wasting?
11. How do you pro-rate your power charges to different departments.
12. Are your department heads satisfied with the method now used for charging them with steam?
13. Do you use the same method for electrical charges as you do for steam?

Courtesy Republic Flow Meters Co. of Canada, Ltd.

PASSING a hand over his forehead, the worried drill-sergeant paused for breath as he surveyed the knock-kneed recruit. Then he pointed a scornful finger. "No," he declared, "you're hopeless. You'll never make a soldier. Look at you now. The top 'alf of your legs is standin' to attention, an' the bottom 'alf is standin' at ease!"

The Vacant Chair

Progress in New Equipment

NEW TYPE OF PLUG VALVE

THE Nordstrom lubricated plug valve is the invention of Mr. S. J. Nordstrom, a mechanical engineer, at the time a resident in Mexico City and engaged in the design, construction and operation of cyanide plants. In the course of this work the obvious defects of standard plug cocks and gate valves for handling cyanide solutions and slimes were very evident, and to remedy these defects the valve now under discussion was devised.

The general construction and characteristics of this valve as made by the Merrill Metallurgical Company, 121 Second St., San Francisco, Cal., will be evident from a study of the accompanying illustrations. The basic principle of the Nordstrom patent is the combination in a plug valve of lubricant conduits and a lubricant chamber at the base of the plug so positioned that when pressure is applied to the lubrication screw, this pressure operates to lift the plug from its seat and simultaneously to distribute lubricant over the bearing surfaces. A flexible packing is provided between the body of the valve and the cover. This packing also rests upon an anti-friction washer forming the thrust bearing of the plug. This thrust bearing is grooved concentrically to prevent leakage. The flexible packing furnishes the necessary elasticity to allow the plug to be forced from its seat for the purposes of lubrication and to force the plug back into its seat when the pressure in the lubricant chamber is released. The location of the lubricating conduits and of the lubricant chamber are clearly shown in the illustration on page 6. A stop is cast as an integral part of the plug and cover and is so positioned that the lubricant conduits can never be exposed to the fluid passing through the valve.

From the construction it will be evident that, no matter how firmly the plug may be stuck to the body of the valve, when force is applied to the lubricating screw, a pressure is created in the grease chamber at the base of the plug, and that this pressure must either raise the plug from its seat or else break the body of the valve.

Suitable lubricants are supplied in the form of convenient cartridges, which fit loosely into the lubricant conduit when the screw is removed. Several grades of lubricant are supplied to suit the special conditions under which the valves may be used.

Nordstrom plug valves are made with a parallel opening through the plug to minimize the friction of flow and to increase the life of the valve. As will be noted from the illustration, the flanged type of valve is constructed along lines which insure a high hydraulic efficiency and this type is recommended, particularly where such efficiency is an object.

Re the Ontario Graded Certificate Act

Correspondence

HONI SOIT QUI MAL Y PENSE

The Editor: I seem to have raised a hornet's nest about my ears for reproving our friend Mr. Noble his undignified remark of a "Wop." I am sorry I have hurt his feelings and apologize, which leaves me a wiser man than formerly. May I ask him, in future, to try and not instil so much venom in the tone of his letters. I must still call his attention to the letter of February 20, where he states that a wop or laborer, etc. This I would say was very inconsistent with his later letter. I would ask Mr. Noble to define or give me a definition of the word technical as applied to modern engineers, also does he think that a man who takes an I. C. S. course comes under the category of technical man. If so I am afraid there is misunderstanding regarding my few remarks. Please do not misconstrue this; a technical man can get the foundation of a technical education from the I. C. S., but he has many weary hours to study and miles to travel before the can come under the category of "the technical man." Please give me this answer and we may come to a better understanding in the future in our exchange of ideas.

The engineer I had in my mind when I wrote that paragraph of a splendid mechanical engineer, is a man of good quality (his moral character does not concern us now); he had charge in his earlier years of one of the largest engineering shops as general foreman, and was noted for his mechanical genius; if given the ordinary formula he could work them out, writes a splendid hand, is a good draughtsman, but he hates slang, and is a gentleman is his conversation and dealings with his fellow men. But (that awful subordinating conjunction) he is not a technical man, so we will say x = technical training (and x is the unknown quantity). Mr. Noble, from his letter, is under the delusion that I am technical from head to toe and not practical; in my last letter he will learn different, for my road as an apprentice through the shops, was pretty rough, but when it was finished I always looked ahead with "Excelsior" as my motto. I have to thank the British navy for my good training as an engineer, for there is where efficiency counts.

I still take my old stand that the majority of engineers do not study enough nor take their profession in the serious light it should be taken; mind, I speak collectively of Canada, and when he has read "Wop's" letter he will see there is some foundation for my assertions "even in Ontario." I may add I do not spend all my time in Montreal, but I would not like to say I have visited such a number of plants, or spoken with hundreds of engineers in Ontario, but in my career as a construction engineer and also as a boiler inspector I have visited a few.

I was rather surprised at his caustic remark on the cheese factory; perhaps he has handled one of these plants, for even there brains can be used. Now, friend, please study the power plant situation in Ontario, their different horse powers, etc., and I think you will begin to see the drift of my remarks on the 2,000 horsepower question. You cannot get away from the fact that there will be more first-class engineers looking for positions than there are positions to fill in Ontario; the 2nd class engineer will monopolise them all. Why should I bother? He will say the 1st class exam. is too hard, and of his own accord he will remain there; my ambition for years has been the uplifting of our profession, but load them gently, not all at once, and the responsibility will be carried easier. This subject is worthy of a sensible discussion, and don't let us fly at one another's throats like the present Members of Parliament when any individual one makes a suggestion. In my remark about a chief who has no technical training I had in mind a 40,000 horsepower plant with its up-to-date equipment. Flow meters, CO_2 recorders, etc., and numerous other things too numerous to mention. Let the said engineer be called upon to make an efficiency test with data up to date, pick out the many errors that can be made through faulty collaboration; this requires a technical knowledge of more than common; in minor plants of 500 or 1,000 we do not expect the same, although the test should be as thorough, but there are a great many engineers in charge of heating and refrigerating plants that call themselves chief engineers who are not deserving of the title. I do not see or find any amusement in the troubles of Ontario engineers. Mr. Noble evidently misconstrues my words; I wish more to help them, and try and point out the pitfalls our province has fallen into and from which I want my brother engineer to avoid; I am sorry I cannot devote more time to Mr. Noble's letter, but must thank him for his sketch of the trap. Is it his patent or does it belong to some of his friends? I will not attempt to pass remarks on it as it is poor etiquette for one engineer to criticize another engineer, especially when he is doing his best, but I would really have liked Mr. Noble to have given us a more technical detail of the trap and its statistics, again thanking him and reminding him at the same time I am always willing to be shown where I am wrong; being an I. C. S. man and of considerable technical ability he should be willing and able to do so.

I would like to meet you, Mr. Noble, for I fancy we should be great friends after the rough spots had been smoothed out.

Now Mr. Editor, to hark back to the old subject, the "Examination of Engineers," from schoolboy days to manhood and through life, that dreaded word examination, no matter what we are trying for, what mysteries does the word enfold (the inward moniter shall I pass) those notes of exclamation: "Oh? it is too hard," etc., so the cry goes on, and now in later years when we are called upon to face that dreaded monster again our brain seems dulled with the shock, yet our success as an engineer depends on it and we approach the examination table with nerves all tingling, the final plunge and the expectation was a hideous nightmare, but the realization was paradise. Our friend Mr. Carmichael writes very clearly on "Memory is a Treacherous Thing." It is, and for any engineer to try and remember all the formulas in engineering would be impossible and would be asking for a first place in the race to the nearest asylum. What are

our engineers' pocket books supplied for? Not for ornament, but to refresh our fagged memories. One of the most difficult examinations in the engineering profession is the British Board of Trade "extra chief." Even here they supply a great many formulas, and I do not think the Ontario examinations will be any worse than that, or even if they come any where near a 2nd class certificate of the British Board of Trade.

I think the real idea is to understand how to break up a formula and find any particular quantity. The majority of examiners generally state a problem in a peculiar way and leave it to your brain to find the proper statement; any uncommon formulas are supplied; the everyday ones we can generally remember with a little thought.

I thank "Wop" for his few words and Shakesperian attitude in defending the poor mechanic without training. According to Mr. Noble's letter we should look for the cream of the engineering profession in Ontario, but "Wop" is sensible and tells us they are merely engineers like other parts of the world. Now I hope the term wop will be eliminated from any of our future discussions, for it is bad form, and very ungrammatical (at least it is neither a noun or an adjective), and from technically educated men very ungentlemanly. I should deem it a personal favor to know the gentleman writing under the nom de plume of Wop, so why camouflage. I must not forget to thank Mr. Elbthon for some of the sympathetic remarks on the nervous movements of chiefs of large plants; he is perfectly correct, they have an awful lot on their minds, which cannot be confided to every one, but as the horsepower grows so do the grey hairs (I do not possess any hair to go grey) but I must plead guilty to being a bunch of nerves at times, due to a former nervous breakdown through excessive study; however, with the man of iron nerve occasions arise when everyone is looking to the chief for the next move in some very grave crisis, when a false move may cause untold damage and loss of life, but as he says, it is not the technical man who realizes the danger, oh no, it is the man who has worked his way from the bottom rung of the ladder and understands the danger signals and steers his plant to safety. The paragraph advising operating engineers not to study too much is a word to the foolish and should not be taken seriously, for it is quite different from that given by most of us, although if a man studies 1½ hours a day he will be surprised how much he can cram into his brain in the course of a year, and don't forget, no study on duty; concentrate your mind on the work, for if you do not, some confounded thing is bound to go awry, and when you wake up and come down to earth—What a mess.

Believe me I have had some, and have scars to show. Before finishing my letter I would like to apologize to the consulting engineers who read POWER HOUSE, especially Mr. Coombs, whose photograph appears in the March 20 issue. He is a personal friend of mine; he called me over the phone after the February 5 issue and asked why are you knocking the consultant? I apologized for I had not such intention. In his conversation he gave me to understand that he wished to be a help to the engineers and try and steer the younger engineer through the rough roads. I hope he may be successful. for he deserves it. Our heads have been together on more than one occasion, his brain dominating.

How different to another person who came under my observation. The other day a friend and I were discussing engineering in general, when the conversation turned to another acquaintance, Mr. Blank, who has just finished his fourth term in college. I remarked what is he going to do and my friend replied: "Oh, he has opened an office and has started as a mechanical consulting engineer." Needless to say my remarks would not look well in print. I think I have taken up my allotted space, but I shall follow with great interest the path of the graded certificate of engineers in Ontario and sincerely hope it may be the means of lifting the status of that body to the pinnacle of perfection and ability and also financially.

HENRY WRIGHT.

THE TRAINING OF THE ENGINEER

Will you permit me to use a bit more of your valuable space? There are several points in a "Wops" letter, March 20th issue, that require a little clearing up. He says, "It would be interesting to know where the deciphering of mathematics and formulae can be acquired." He had the answer before his eyes when he was reading POWER HOUSE. It is impossible to read any one number without absorbing considerable technical knowledge, including some part of mathematics and rules or formulae, complete instruction in the theory and practice of power plant management and operation has been given in former numbers of POWER HOUSE. There are also a number of reliable correspondence schools which give first class instruction along this line to anyone who can read and desires knowledge and who will study a few minutes each day. "Wop" tells us he learned the rule of three. If he uses the rule in connection with questions dealing with power plant men, money or material, he is using technical knowledge. The man who can read and write, who can do addition, division, multiplication and subtraction, can learn a great deal about the theory and the technical part of power plant engineering in a few weeks with little study.

The only power plant man who has the slightest claim to consideration for being completely ignorant of the theory of engineering is the man who cannot read. There are so many good power plant journals, any one of which only costs a few cents a month, that the only excuse any man who can read can give for being in such a condition is because he is so full of conceit that he thinks he knows it all.

The trouble may be that the ignorant man is contented. Contentment has been defined as stagnation when applied to engineering. The real artist is never completely satisfied with his work, be he a pick and shovel trench digger or a portrait painter. In the former case he feels that if he had taken a little more care he could have made a trench straighter and the sides more even.

In the latter case the workman is sure he could have improved on the tints if he had been more careful. If a man is contented he will never exert himself to help others or do any unselfish act.

When I was at school my teacher once told me to always try to do the problems I thought I could not do, and I would often be surprised to find that they were quite simple. Anyhow it is better to aim high and fail than to aim low and succeed. Surely the men who can read and have never learned anything beyond what they were compelled to learn are no high aimers. If a man can figure out the horsepower of a steam engine he has some technical knowledge. If he knows why the steam piston is larger than the water piston on a pump, he has some knowledge of theory. In fact it is practically impossible for any man in charge, or assisting to operate, a power plant, to be absolutely ignorant of the theory of some part of the equipment, even if he never read one word about engineering.

Understand, the man who understands theory only is not in the same class as the good practical man. Nevertheless, the good practical man's value is more than doubled when he has a wide knowledge of the theory of engineering. Unless a man desires to secure first class papers in a purely techincal knowledge test a knowledge of simple arithmetic is all that is required to understand and work out countless rules and formulae.

JAMES E. NOBLE.

In your March 20th issue of POWER HOUSE, a correspondent signing himself a "Wop" is peeved because engineers with no engineering knowledge outside of that secured by personal operating or practical experience is called a wop or laborer. The following extracts are taken from an engineering text book by N. Hawkins, M.E. Quite recently a distinguished professor of Harvard University published an article in which he grouped the engineers now working side by side for the development of our material resources into three classes. First, those men, many of them eminent in the profession, who are the product of the workshop, whose experience and education have been obtained entirely in the field or workshop, and from any text books available.

Second.—Men who have graduated from literary or natural science departments of colleges and have learned practical engineering after leaving their classes—drawn to it by a strong taste for the profession or by the pressure of circumstances.

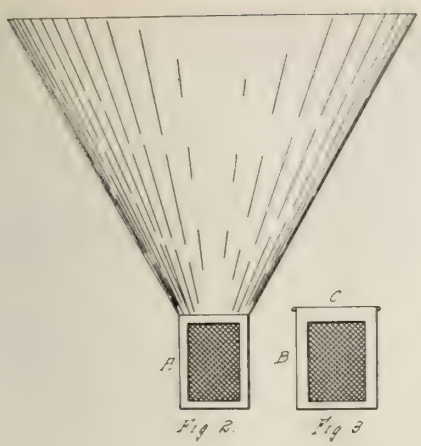

Fig 2. Fig 3

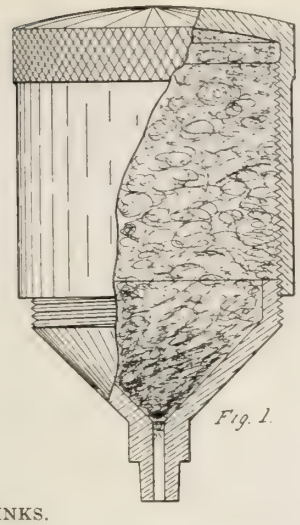

Fig. 1.

POWER PLANT KINKS.

Third.—The younger men, graduated from schools avowedly technical, or from technical departments of universities. These men are gradually supplanting the other two classes, as the demand for greater attainment and better education increases, and as competition and the invention of labor-saving machinery turns the mechanic into a laborer and raises the status of the educated engineer. The next generation, the professor believes, will see the men with only practical or academic training practically cut off from all large modern power plants as chiefs of same.

JAMES SCOTCH.

EMERGENCY MEASURES

There are many simple ideas in use in power plants, the only reason they are not more generally known is because those using them consider them so simple that most any one would know them, their very simplicity is one reason for their limited use,, for it is the very simple idea that is often the last to come to a person's mind. One such idea is shown in Fig. 1. Often times the supply of grease for the compression cups runs out and a hurry call for more is sent in. The grease shortage can be overcome by filling the grease cup with waste or sponge soaked in cylinder oil, screwing down just as if grease was in the cup.

Fig. 2, Shows an oil straining funnel that can be made at a small cost, and it gives excellent results.

The outlet is made about 3 inches in diameter, pieces are cut from opposite sides and a covering of brass gauze soldered over the holes, this itself makes an excellent strainer as most of the dirt will settle on the bottom which is closed and has no screen on it. The piece shown in Fig. 3, is made to slip over the part A, it also has brass gauze as at B. When using B a piece of cheese cloth is laid over it at C, and pulled over the part A, the oil has often to pass through the two, brass gauze and cheese cloth; and, believe me, it is mighty little sediment that will get through.—James E. Noble.

THE SYNCHRONOUS MOTOR AND REFRIGERATION

(Continued from page 181)

improperly and which provides protection from loss of voltage and over loads.

The fourth panel carries the following instruments for the main circuit; power factor meter, ammeter, voltmeter, graphic wattmeter, and integrating wattmeter. The two right-hand panels control the light and the small motors throughout the plant.

An excellent example of the superior economy of the synchronous motork as compared with the steam engine, for driving ice machines is the installation in the Manhattan Street dairy of the Sheffield Farms Company, New York, where 80,000 quarts of milk are handled every day.

This plant contains four 80-ton Newburg ammonia compressors, and a 12-ton York compressor, which were driven by steam engines before the war. After the Americans went to war, however, fuel was hard to get, its price rose rapidly, and the Government ordered all inefficient engine-driven ice plants to be closed down. The necessity of making some change in their drive was realized by the officials of the Sheffield Farms Company, so they decided to use an electric motor and obtain power from the local lighting company.

The present drive, which is shown by the illustration, consists of a 500 H.P. Westinghouse synchronous motor, operating on a 440-volt, 60-cycle circuit, and which has a speed of 350 r.p.m. This motor is belted to a line shaft, from which all of the compressors are driven and, in addition two 14 x 10 inch air compressors and two generators of 110k.w. and 125 k.w. respectively used for supplying current for local lighting. Current is supplied by the *m*nited Electric Light & Power Company.

While this installation, being originally planned for engine drive, is not arranged in an ideal manner, nevertheless the officials state that the efficiency of the motor supplied with central station power is so much greater than that of the older drive that its savings and increase in capacity amount to $30,000 a year.

One of the interesting features of the installation which is now recognized to be great importance in ice-plant management, is the careful attention given to the graphic meter chart which shows the amount of power being used. Since the load is practically constant under given conditions, the curve drawn by the meter should ordinarily be a straight line. But any variation in the factors of production, such as, the depreciation of any part of the machinery, a change in the temperature of the brine, water, etc., or the alteration of any other, detail, at once changes the power demand which is noted by the meter. An investigation is immediately madde as to the cause of the variation and correction is applied as soon as possible. Thus the efficiency of the plant is kept maximum at all times.

The use of a synchronous motor, instead of an induction motor, for this installation is in line with the present tendency in refrigerating engineering practice. The synchronous motor is favored because of its high efficiency, uniform speed, and ability to improve the power factor of the electrical system in the plant; and an ammonia compressor is well adapted to be driven by this type of motor because, with the use of by-passes, the starting conditions are light and the speed is constant.

At the Sheffield Farms Plant, 110 tons of ice are produced daily from purified and filtered city water.

THE ABSORPTION SYSTEM OF REFRIGERATION

(Continued from page 181)

as nearly level as possible with the lower flange joint of the shell and head. The shell condenser should show from 4 to 6 inches in the gauge glass while the receivers of atmospheric or double pipe condensors must contain sufficient liquid to cover theoutlet to the expansion valve so that gas cannot blow through. In the brine cooler there should be sufficient anhydrous ammonia to frost both gauge cocks; the gas line should be slightly frosted back to the absorber, but frost showing on the purge line indicates that liquid ammonia is being carried out of the cooler, which condition should be promptly remedied. Care must be taken in handling the anhydrous ammonia cylinders. The manufacturers instructions should be carefully followed either in charging or in withdrawing ammonia into cylinder as an over full cylinder is a source of great danger.

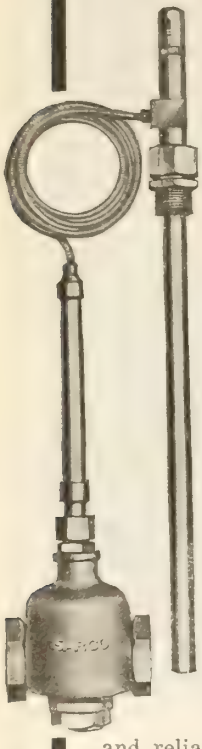
An ALL-IN-ONE Temperature Regulator



Here is a temperature Regulator that is entirely self-contained and self-operated. It requires no exterior operating means such as electricity, compressed air or water. It necessitates no involved connections or complicated attachments which require constant adjustment and cause trouble.

Sarco does its work by itself and does it accurately and dependably. It is simple and compact.

SARCO controls the temperature in the natural and reliable way — by utilizing liquid expansion and contraction.

A heavy hydro-carbon oil surrounds a spirally corrugated metallic tube. When the temperature reaches the point at which Sarco has been set, the oil expands. This produces pressure on the corrugated tube and operates a valve that at once shuts off the heat. It operates reciprocally when the temperature falls below the desired point.

That's all there is to it. Sarco effects a saving in first cost, a saving in installation cost and a saving in labor.

Sarco Regulators are also supplied for room control.

We ship the Sarco Temperature Regulator on a 30-day free trial.

May we send you Booklet J-54?

ANNOUNCEMENT

Mr. E. C. Hanson, president, announces the organization of the Republic Flow Meters Company of Canada, Limited, and the establishment of the head office at 145 Wellington Street West, Toronto, Ont. This company has been organized for the purpose of handling the Canadian business of the Republic Flow Meter Company of Chicago and to give a service superior to that possible through agencies. A complete stock of meters and parts will be carried in Toronto and the new company will be in a position to supply without undue delay any demands made upon it. Mr. Hansen is in charge at the above address.

AMALGAMATION

Special meetings of the stockholders of J. H. Williams & Co., at Brooklyn, N. Y., and of The Whitman & Barnes Manufacturing Company at Akron, Ohio, have been called for April 2, for the purpose of ratifying an agreement entered into by their respective presidents, made subject to the approval of the stockholders, for the merging of the Chicago, Illinois and St. Catharines, Ontario plants of The Whitman & Barnes Manufacturing Company with J. H. Williams & Co.

When ratified, this plan will contemplate the operation by J. H. Williams & Co., of drop forging and drop forged tool plants at Brooklyn, N. Y., Buffalo, N. Y., and West Pullman, Chicago, Illinois, in the United States, and at St. Catharines, Ontario; and the business will be operated by the individuals now connected with these plants.

The plants of J. H. Williams & Co., under this arrangement, call for a considerably extended business, and for the service of all their customers in the location most convenient to them.

Crude Oil Engine For Sale

90 H.P.—built by the Blackstone Company who are the recognized leading manufacturers of Crude Oil Engines. All in splendid condition and can be inspected set up. Complete with 60 KW, 550 Volt Generator, if so desired. This is an opportunity to get an economical power installation at attractive price to immediate purchaser.

Address:

Williams & Wilson, Limited
84 Inspector St., Montreal, P.Q.

OPPORTUNITIES

Freezing System For Sale

Complete — 12½ tons capacity, c o n t aining cooling coils; covers and framed work; crane; hand hoist and can dump.

GUNNS LTD., West Toronto, Ont.

FOR SALE

One 45 K.E. Generator complete, $600.
One 65 H.P. Motor, 220 Volts, complete, $600.
The above machines are perfect.

Minimax Electric Co.
323 3rd Ave., Maisonneuve, Montreal
Phone La Salle 1797

FOR SALE

One 300 H.P. Leonard Automatic Engine; one Closed Feed Heater; one 8 H.P. 220 v. D.C. Motor; one 15 H.P. 220 v. D.C. Crane Type Motor.

H. N. BROWN, New Glasgow, Nova Scotia.

HELP WANTED.

DESIGNING ENGINEER—IF YOU ARE EQUIPped to take hold of an established line of Pressure Reducing Valves and push them to perfection, you have an opportunity before you. Answer clearly and fully on the following points.

(1) Have you basic knowledge of designing and actual experience? This is absolutely essential.

(2) Can you design special Valves such as Relief, Globe, Check-Reducing Valves for High Pressure. Any experience?

(3) As designer and Production Engineer, could you take active charge of mechanical end and maintain maximum production? Any experience?

(4) Give age, experience, full references, and salary expected. Strictly confidential. Will not write references without your consent.

The business is established, located in the Middle West. A good paying proposition with a bright future. Write immediately. Apply Box 1, A.P.H., Power House, 143 University Ave., Toronto.

WANTED—5 TO 7½ H.P. A.C. 25-CYCLE 110-volt Induction Motor in good condition. Box W.F.S., Power House, Toronto.

Better Jobs— Bigger Salaries

Let These Men Show You How to Get Them

Are you interested in sure and rapid advancement to a really worth while position in one of the best paying professions in the country today? If you are it will pay you well to read this announcement. It tells how you, with or without previous training, can prepare yourself in a short time for an attractive position that insures a lucrative salary and an assured future.

Remember—this profession is a new one—unlike all others, it is still uncrowded—and the demand for trained men far exceeds the supply. That's why your services will be in demand when you have acquired the necessary training. That's why you can count every effort a sure and wonderfully profitable investment.

Easy to Learn— No Experience Necessary

In most professions, to become proficient, long periods of intensive study, followed by years of hard training, are necessary. In this new profession—Combustion Engineering—the necessary training can be acquired in a few short months. Why? Because all the knowledge and experience—all the scientific research and experiments—all the labor and study of seven of America's leading Combustion Engineers have been condensed and classified to such a remarkable extent that what formerly required years of study can now be learned in a fraction of that time.

This training from the very first can be applied to the practical every-day problems of any power plant. At some point in the course you must spend some time in power-plant work if you have not already had the experience. That may prove to be your field or you may make it the stepping stone to an executive position. In either case your services will increase in demand and value as you progress in the training.

America's Leading Combustion Engineers Teach You

On this page are photographs of our educational staff. Probably you know some of these men personally. At least, all or most of them, are known to you by reputation.

Jos. W. Hays is the author. His reputation as a writer on Combustion Efficiency is world wide. In this course he has surpassed himself. Every lesson, every chapter, is written in such an interesting, comprehensive way, that the reading of the course is as pleasant as it is profitable.

Associated with Mr. Hays as reviewing and advisory editors are **I. E. Moultrop, W. L. Abbott, Jos. Harrington, Fred R. Low, David Moffat Myers, Prof. S. W. Parr and Arthur L. Rice.** These names alone are proof positive of the thoroughness and completeness of the course.

Especial attention has been given to make this course easily understood by everyone. It is stripped of all unnecessary technicalities and is written in a way that you can quickly grasp and understand. It is prepared especially for the man on the job—the busy man in office or boiler room who can commence putting his knowledge into practice the moment he starts the course.

Send for this FREE BOOK—TODAY

To enable you to get a better idea of just what this course is—just what it covers—why it is a guide to a better job and a bigger salary—why it enables *you* to cash in on the big salary awards that fall to the Combustion Expert—to make all these things clear to you, we have prepared the book "Opportunities for the Combustion Expert." Send for a copy of this book today. It's free.

Mail the Coupon

Simply fill in the coupon and mail it to us. We'll send you a free copy of "Opportunities for the Combustion Expert" by return mail. Time is valuable. Get started today while the opportunities are greatest. Mail the coupon—Now.

Pot Valve Boiler Feed Pump

Team Work in the Power Plant

TEAM WORK is just as essential between working apparatus in the power plant as it is between men in the shop. Between men, team work is a matter of training—between machines, it is a matter of "picking 'em right" and fitting them to the job.

Services vary so, that to satisfy them requires an immensely wide range of apparatus for selection—and that's where Worthington comes in. Through a period of 80 years in industry Worthington has developed apparatus that will fit any power plant need, no matter what the requirement or duty. Whether a single pump or a complete layout, Worthington has the right type and capacitied apparatus and the engineering experience and knowledge necessary to correct installation. There is hardly a problem in power plant equipment that Worthington cannot successfully solve with Worthington apparatus.

The freely tendered engineering service is yours at request and without obligation.

Jenkins Valves

In every part of the World you will find Jenkins Valves the standard. They are recommended by leading engineers because of their modern design, quality of material and absolute dependability under the most severe conditions. They require the least attention and have the lowest maintenance costs. They have been "quality" equipment for half a century.

Long experience has developed the perfect design of Jenkins Valves. Each part is scientifically proportioned to its duty, has the excess weight and strength that mean dependability. Every Jenkins Valve—and there's a valve for every requirement—has the same superior qualities.

Make sure on your new equipment — specify Jenkins Valves, and see that the valves you get have the Diamond Trade Mark cast on body.

The Safe and Certain Boiler Cleanser

PUT a barrel of BOICO in your boiler room. It's the most efficient and economical **clean-boiler insurance** you can adopt. BOICO routs the most stubborn cases of boiler scale formations quickly and thoroughly.

Hundreds of Plants are Using BOICO Every Day With Unqualified Success

What BOICO will do in one plant it will do in another—**it will do in yours.**
BOICO loosens and brings away the hardest of old formations and keeps new scale from gathering. Yet it never does the slightest injury to boilers, valves or packings. Neither does it carry over in the steam, nor cause foaming or priming.

We are confident that BOICO will live up to all our claims and are prepared to let you test it FREE of cost. You have nothing to lose by trying it—let us hear from you.

Anti-Clinker Shell Bar Grates

There's no coal waste where these grates are used. Maximum air-space provides for perfect combustion. No clinker formation here, and you get more heat with less fuel.

One-Piece Jointless Furnace Lining

Why shift the blame on your engineer or fireman when it is your furnaces that are not up to the highest point of efficiency? USE PLIBRICO—it lasts longer than fire brick and is easier to instal.

Tip-It Patent Welding Process

With TIP-IT you get tools with shanks of carbon and tips of high-speed steel.

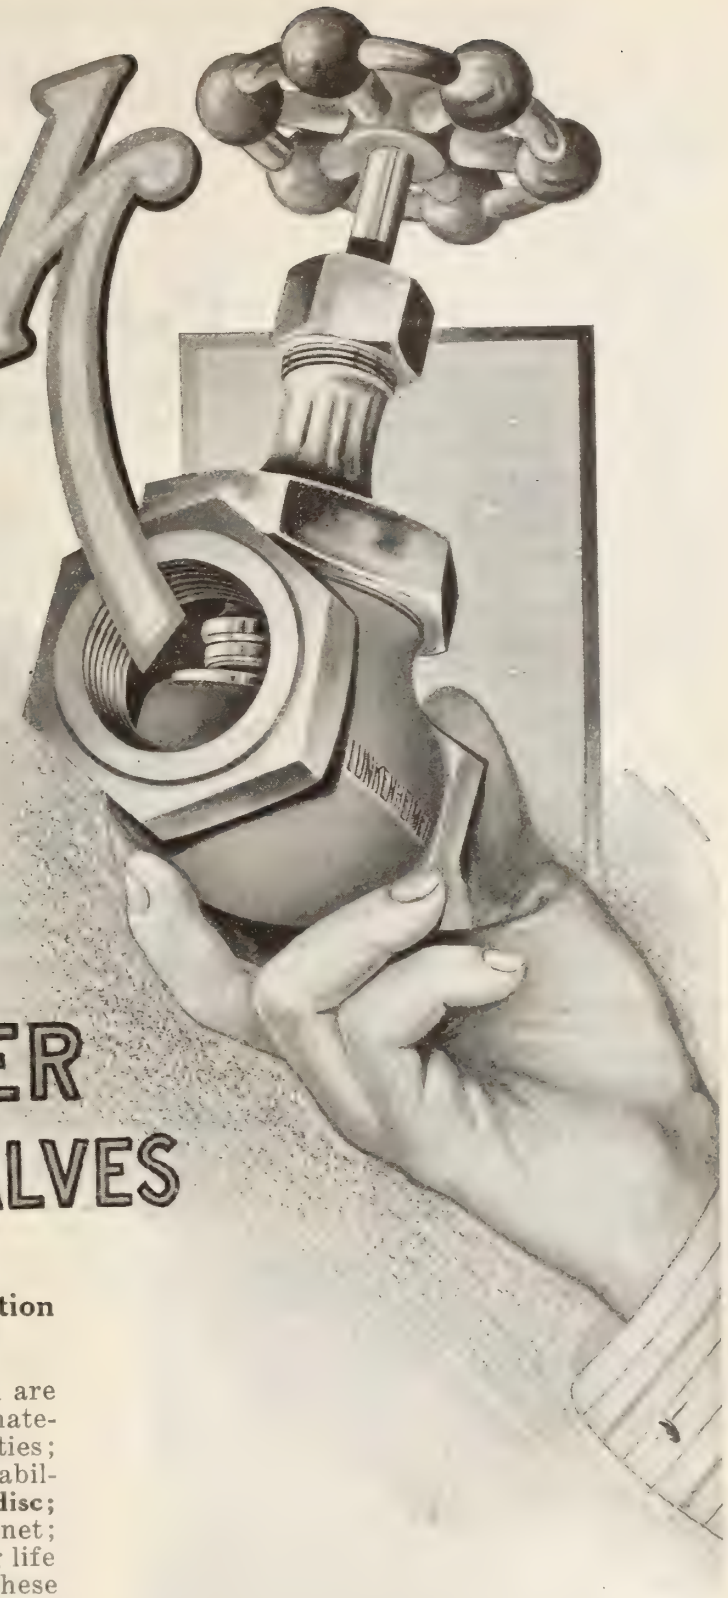
Your Jobber Has Them

Manufactured by DART UNION CO., LTD., Toronto, Ont.

Look



and satisfy yourself of the many advantageous features embodied in

LUNKENHEIMER "FERRENEWO" VALVES

The body is made of a Ferrous Composition specially alloyed for these valves.

Note the **seat ring** and **disc,**—both of which are made of Lunkenheimer "Valve-nickel," a material having exceptional wear-resisting qualities; the regrindable seating surfaces, the renewability of all parts, including the **seat ring** and **disc;** the full areas through the body; union bonnet; special composition stem, which insures long life to the stem threads; deep stuffing box, etc. These features combined with Lunkenheimer "quality" materials and workmanship make the "FERRENEWO" **the** valve of exceptional merit. Globe, Angle and Cross, and Horizontal and Angle Check Patterns, for working steam pressures up to 150 pounds.

Your local dealer can furnish them; if not, write us. Write for descriptive Booklet No. 576-DC.

For Economical Coal Handling In Power Plants Install

Jeffrey

Steel Apron Conveyers

For more than a quarter-century JEFFREY engineers have been in intimate contact with the material handling needs of the industrial world. The experience gained has enabled them to design and standardize conveying units which will fill satisfactorily the conveying needs of every industry.

The advantages gained are the elimination of special design, the saving in manufacturing costs, and the practicability of maintaining a permanent stock of standard units.

Our new Catalog No. 258-4 explains clearly how you can select a standard JEFFREY Conveyer which will solve your "special" problem. Write TO-DAY.

Canadian Branch and Warerooms: Montreal

What protection do you provide your men against the hazards of Ammonia Fumes?

Wherever there is a refrigerating machine there should be a

BURRELL Ammonia Mask

Protection from ammonia fumes is positive, quick, simple and easy with the BURRELL.

It makes possible the immediate repairs of the most serious breaks — even in fumes so heavy they would blister the skin.

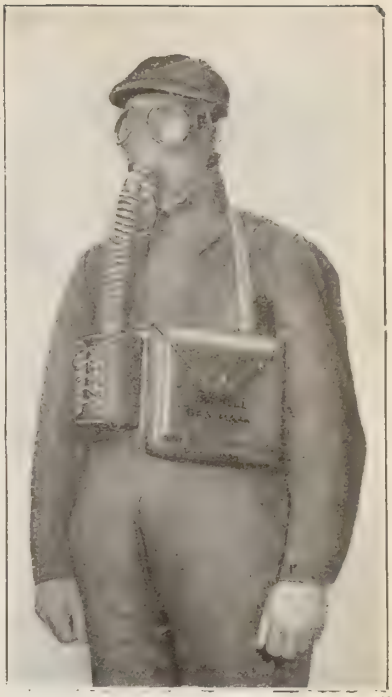
The Burrell has every feature for safety, for convenience, for ease and efficiency. A single high-duty canister, free from all complications.

In use in big city fire departments, in the larger packing houses — one company recently installed 121 additional Burrell Masks.

The BURRELL CANISTER

has longer life, greater efficiency, than any other Ammonia Canister ever built. You can use it with any mask. Order the Burrell for your "spares."

Write to-day for descriptive folder giving full details. Immediate shipment from our factory or branches.



This man can go into dense Ammonia Fumes—he can work in comfort and safety

Here's Another Efficient Silent Chain Drive

700 H. P., 8ft. Centers

A LEATHER belt drive could never transmit this large amount of power on such short centers, yet Link-Belt Silent Chain transmits the power with highest efficiency. It combines the best points of the leather-belt drive with the positive action of the gear drive. It is more efficient than either.

Probably you have a machine which could be operated more efficiently by a Link-Belt Silent Chain Drive. Send for one of our Drive-Chain Engineers and get his recommendations. Also write for our 128-page Data Book No. 125.

Place X in Square

Reduce Your Fuel Bill

In a series of tests made by eminent mechanical engineers it was shown conclusively that 10% to 40% of the heat units of coal are lost, due to leaky boiler settings that allow an excess of cold air to enter the furnace or combustion chambers.

BETSON'S REG. U.S. TRADE MARK PAT. OFF. PLASTIC FIRE BRICK

Makes it easy for anyone to mould into place a solid, one-piece, monolithic boiler setting lining that is jointless, airtight and capable of withstanding the stress and strain because expansion and contraction have been neutralized.

With airtight linings and gastight baffles you not only save the 10% to 40% of wasted heat units, but reduce the repair and upkeep costs in your boiler room as well.

Betson's Plastic Fire Brick linings outlast other linings not only because of high quality and experienced compounding, but for the very logical reason that in the one-piece lining there are no bricks to work loose or joints to open up.

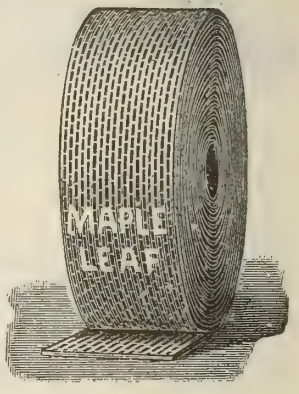
Dominion Belting Company, Limited
Hamilton, Canada

Sole Manufacturers of the celebrated "MAPLE LEAF" Brand Stitched Cotton Duck Belting and Belt Dressing.

The demand for our products has steadily increased because the standard of quality has been maintained.

We make only one grade, the best that can be produced.



"MAPLE LEAF" is the strongest, truest running, most economical and efficient belt on the market for transmission of power, conveying, etc.

Being thoroughly waterproof it is suitable for running in wet or dry places. **"MAPLE LEAF"** Belt Dressing is different to others offered in that it is equally good for all kinds of belting, leather, rubber or Balata, as well as our own make.

Write us for prices, and if desired we will be pleased to furnish samples and further information.

A trial order will convince you of their utility.

DOMINION BELTING CO. Ltd., Hamilton, Canada-Quebec Branch: 51 Duluth Bldg., Montreal

HOMESTEAD
Quarter-Turn Valves

The Most Simple and Effective of All Valves

A quarter turn only, and a Homestead Quarter-Turn Valve is changed from absolute tightness to a straight unobstructed flow. Ordinary globe or gate valves require from six to ten turns of the wheel! Is it any wonder that Homesteads have replaced the globes and gates in hundreds of plants?

Homestead Valves are made in Straightway, Threeway and Fourway patterns. They are used for air, steam, water, oil and acids with perfect satisfaction.

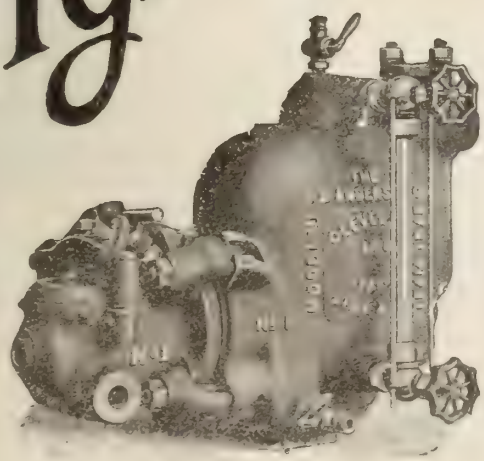
Stays Tight

The ANDERSON
Model "D"
Steam Trap



Just think of the satisfaction you have once this perfected trap is in your steam-room!

Tight from the day you put it in! Of that you can be sure.

It is operated by a counterbalanced Lake Superior Copper Float. Its large air valve is ever under deep water seal, and never will it wire draw.

Furthermore, every part is machined to solid gauge. Self-contained strainer and self-contained by-pass are Anderson features. Note the outside gauge glass. And the simple design! It gives you complete accessibility to every part.

Write for full particulars.

The V. D. ANDERSON COMPANY
1935 West 96th Street, CLEVELAND, OHIO

CLINTON CEMENT

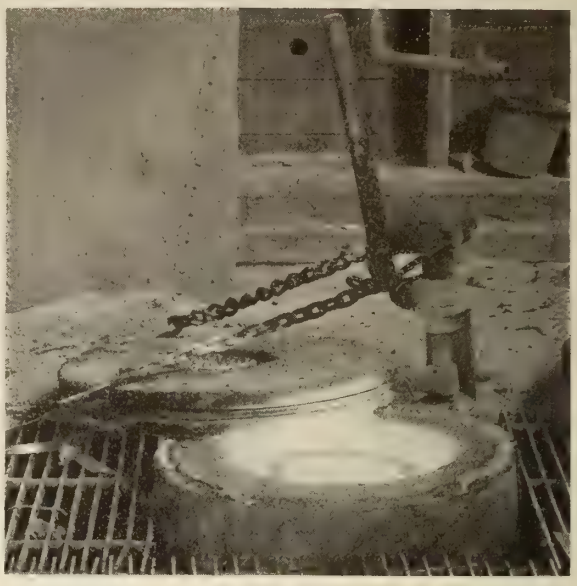
To Withstand Such Conditions As These!

The condition that exists in a brass furnace like this, is a real test for the refractory lining. The enormous temperatures, the expansion and contraction—only the finest linings can stand up under it.

The success with which Clinton Cement meets such conditions, is due to the unusual properties procured by our process of manufacture. Clinton sets to a flexible, glass hard surface which is unaffected by temperatures up to 3,000° F.

For all refractory work, particularly that which usually gives trouble, use Clinton Cement.

A five pound trial tin will gladly be forwarded upon request



Clinton Cement Joints Are Superior to Fire Clay Joints.

Standard Machinery & Supplies Limited
261 Notre Dame St. West, Montreal

TWO FACTORS

determine the value of a paper's circulation to the advertiser—quality and quantity.

The quality may be judged by the methods of obtaining subscriptions.

The quantity may be known absolutely by an independent and expert audit of the circulation records.

Both points are covered by the reports of the Audit Bureau of Circulations.

The advertiser who buys space on a business basis asks for an A. B. C. statement and studies it.

If an advertiser who does not demand an A. B. C. statement conducted the other branches of his business on the same method, he soon would not have any business to conduct.

An advertiser is entitled to the facts. An A. B. C. paper has nothing to hide.

The A. B. C. report of POWER HOUSE will be sent to advertisers on request.

"A little learning is a dangerous thing".

You will know **how to buy intelligently,** only when you know **where to buy.**

The **Arrow** has a point for you.

Kellogg Chimneys

The Logical Selection for Your Power Plant

Made of Corrugated Perforated Radial Brick

Foremost Method of Chimney Construction

Kellogg Chimneys are the logical selection for your power plant for the reason that they represent the most advanced ideas in chimney construction. The **corrugated** feature of Kellogg Chimneys offers a big advantage over other chimneys.

Tests have proven conclusively that the adhesion between mortar and Kellogg Corrugated Brick is 62½% greater than between mortar and ordinary straight or plain-sided brick.

Kellogg Bricks are shaped to proper radius, and in addition they are moulded with vertical perforations, permitting thorough burning, so increasing their density and strength and reducing weight.

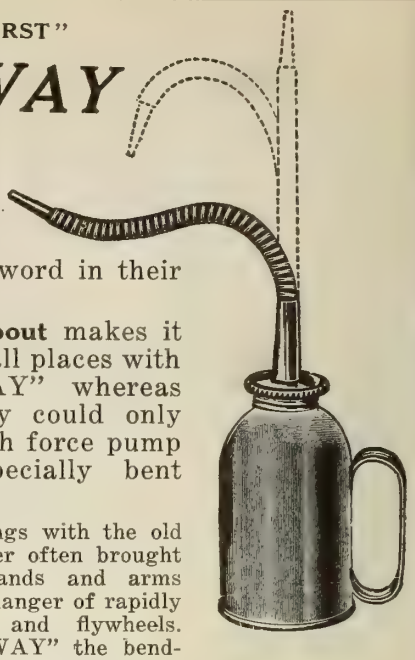
"SAFETY FIRST"

ALL-WAY
RAILWAY
OILERS



are the latest word in their line.

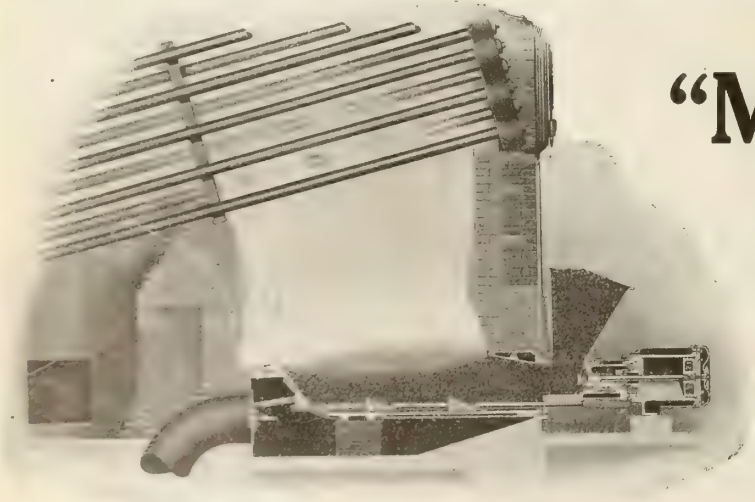
The **flexible spout** makes it possible to oil all places with one "ALL-WAY" whereas previously they could only be reached with force pump cans with specially bent spouts.

Lubricating bearings with the old straight spout oiler often brought the engineer's hands and arms very close to the danger of rapidly revolving gears and flywheels. With the "ALL-WAY" the bending of the spout removes this danger. Sizes: No. 4, 1 pint—10-in. spout. No. 5, 1 quart—11-in. spout.

If your dealer cannot supply you write us.

We also manufacture the well-known "All-Way" Oil Can—saves you 50% of your oil bill.

THE ALL-WAY OILER MFG. COMPANY
196 KING STREET WEST - TORONTO, ONTARIO



"More Steam"

The demand for steam is steadily increasing—and fuel, in addition to being more expensive, is not of a higher grade. Have you noticed the effect of this on **your** boiler plant? Are there complaints of no steam? Is your coal bill steadily mounting? If so, you have need of a

JONES UNDERFEED STOKER

A Jones Stoker equipment will increase the steaming capacity of your boiler—with an immediate saving of 15 to 20 per cent. over your regular hand-fired conditions.

The Jones Underfeed Stoker will save you as much as **one ton in every five**—and keep your chimney smokeless. Isn't this worth investigation? Let us send you full particulars without delay.

Jones Underfeed Stoker Company, Limited
37-41 Britain Street, Toronto

Where Performance Outweighs Price

When required for only a few minutes' occasional use, a low-priced, low-efficiency hoist or trolley may be an economical buy. But for steady, every-day service, the most efficient hoists and trolleys have always been the best investment, and now that labor costs are so high, they are the only sound one. This principle points straight to

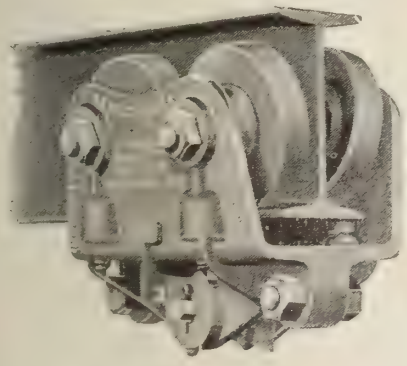
"CYCLONE" High Speed Chain Hoists

When you see the remarkable mechanism of the Cyclone Hoist—how it gets leverage and power without the use of any small gears or pinions—you will understand why it will lift a load with more speed and less effort than any other chain hoist made.

There is less friction—no vibration—just a smooth, easy motion that reduces wear to a minimum, with the result that the Cyclone runs as well after years of service as when new.

Cyclone Hoists are made in sizes from ¼ ton to 40 tons—all sizes as single, self-contained units. Would you be interested in a descriptive booklet or in a demonstration of one of our working models?

Fit running mates for Cyclone Hoists are



"Matchless" Trolleys

The flangeless track wheels of the Matchless never cramp or bind. The trolley is kept in line by free-running vertical guide rollers, adjustable to I-beams of different widths, and the wheels turn on hardened steel roller bearings.

Made plain and geared, in sizes from ½ to 12 tons.

We also supply combined trolley-hoists, single and double I-beam travelling cranes, jib cranes, hand and power winches, trolley frogs and switches, and special hoisting and conveying equipment to suit customers' requirements.

DEPARTMENT OF LABOUR
Ontario Government

Minister: Hon. W. R. Rollo — **Deputy Minister: W. A. Riddell, Ph.D.**

NOTICE TO STATIONARY AND HOISTING ENGINEERS AND STEAM PLANT OWNERS

Everyone operating a **Stationary** steam plant of 50 B.H.P. or over, and everyone operating a **Hoisting** steam plant working at a pressure of 20 pounds or over, irrespective of horsepower and used for hoisting in structural operations or excavating purposes, in the Province of Ontario, must hold a certificate from the Board of Stationary and Hoisting Engineers. Application forms will be forwarded upon request.

After January 1, 1920, all stationary steam plants in the Province of Ontario must be registered with the Board of Stationary and Hoisting Engineers. Application forms will be forwarded upon request.

All applications should be mailed to the Chairman of the Board. W. C. McGhie, Department of Labour, 15 Queen's Park, Toronto.

NOTICE TO MANUFACTURERS, DEALERS AND USERS OF STEAM BOILERS

All steam boilers built in, or entering, the Province of Ontario, and boilers exchanged or repaired, are subject to Government Inspection as prescribed in the Steam Boilers' Act, 3 George V., ch. 61.

Before any work of repair or alteration is commenced on any boiler, notice must be sent to the Department stating the nature and extent of the repairs or alterations proposed to be made. If the Chief Inspector should consider such repairs or alterations of an extensive character, the boiler must be inspected in accordance with the Regulations by an Inspector authorized under the Act.

All communications should be addressed to the Steam Boiler Branch, Department of Labour, 15 Queen's Park, Toronto. D. M. Medcalf, Chief Inspector of Steam Boilers.

Tough as a Tire Tread—
This Hose Cover

IN mines, quarries, tunnel work, shipyards and structural steel work, the tough cover on Goodyear Air Drill Hose and Goodyear Pneumatic Tool Hose has resulted in more work and a lowering of hose cost.

The life of hose in this work depends about 75% on the cover. Dragged over rock and ore and steel girders, tramped on and run over, it takes a tough and well-designed hose to give any length of service.

We have records of Goodyear Air Drill Hose in constant service for 18 months to 2 years.

The cover of white rubber is as tough as a tire tread. It is extra thick. It wears long, even under rough handling.

To balance such a good cover is a specially developed, oil-resisting inner tube; and fabric of extra strength.

So good are Goodyear Pneumatic Tool Hose and Goodyear Air Drill Hose that five-ply is found as satisfactory as six or seven-ply of old-style hose.

The thoroughness with which Goodyear Air Drill and Pneumatic Tool Hose has been designed and built, is paralleled in every kind of Goodyear Industrial Hose. The problems of each industry have been studied carefully. The solution to those problems has been worked out in the Goodyear laboratories. The Goodyear Industrial Hose man has a mighty interesting story to tell to industrial executives. No obligation on your part if you have him call. Just phone, wire or write the nearest branch.

Your Next Boiler

Most successful Plants have devised "wrinkles" and "betterments" of their own which have given them an outstanding position in their respective industries. We have our full share of them, which is perhaps only what you would expect from a firm like ours with 35 years of experience and the reputation for Quality, Workmanship and Service which our products enjoy. All of which should be taken into consideration when you place your next Boiler order.

The Beginning—

A Good Hide

D. K. McLaren Leathers

Good from Start to Finish

The Hide

Selecting the hides is a very important item in the making of D. K. McLaren's Belts. The greatest care is taken to use exclusively the **FLAWLESS BACKS** of the hides of the choicest steers.

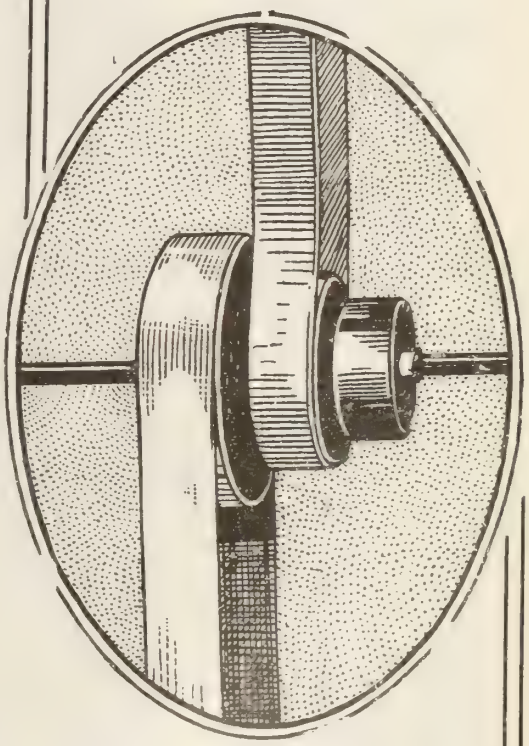
The Tanning

Genuine British Oak Tanning. Therein lies the secret of the toughness and durability of McLaren's Leather Belting. The British Oak Tanning Process is the best process known for preparing belts for hard service. Every bit of the hide's natural strength is preserved.

The Finished Product

Belt slipping is reduced to a minimum by the use of D. K. McLaren's Leather Belting. It transmits all the power a leather belt can transmit. Good quality makes it practically stretchless. Time, labor and attention are saved wherever it is used.

To know what others think of it, write for list of users, then ask them.



The Completion—

A Good Belt

GENUINE OAK

D·K·McLAREN LIMITED

Showing ease with which Pilbrico is laid in place.

Use PLIBRICO

In Building Your Boiler Furnace Lining

It will outlast any fire brick. An ideal material for front door arches, side walls, combustion chamber linings, bridge walls and baffles. It's jointless. Makes your furnaces Airtight and Saves Coal.

Shipped in steel containers only. Warehouse stock carried in principal cities for immediate delivery.

Write for book on furnace building.

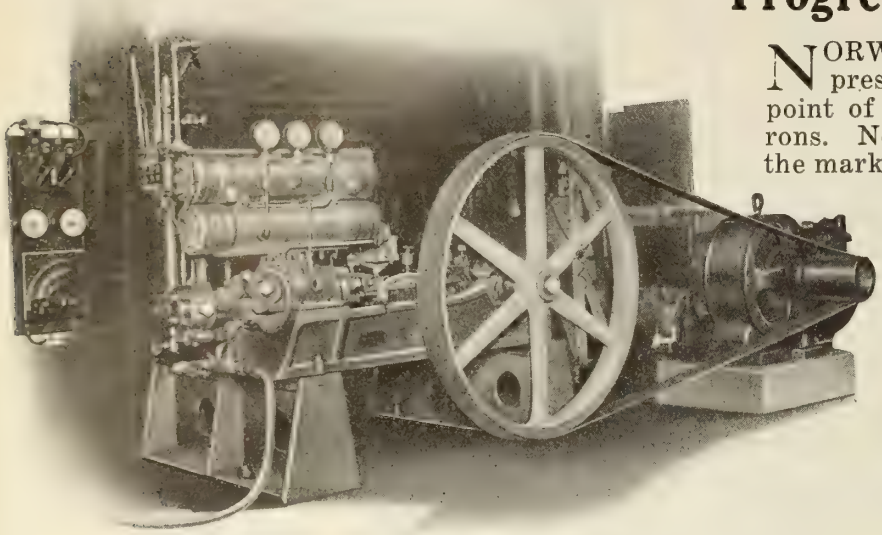
NORWALK
AIR & GAS · COMPRESSORS



A NORWALK COMPRESSOR ON TESTING STAND

Progressive—But Cautious

NORWALK designing of air and gas compressors is progressive—but never to the point of experimenting at the expense of patrons. New features do not find their way into the market on Norwalk machines until they have made good in the factory under long tests—three times as severe as any you will ever be able to impose in actual service.

When considering the purchase of a compressor for any kind of service investigate Norwalks. Bulletins on air, oxygen, hydrogen, crabolic acid gas or acetylene mailed on request. Write for the ones you need.

Put a Farnsworth System to Work in Your Steam Plant

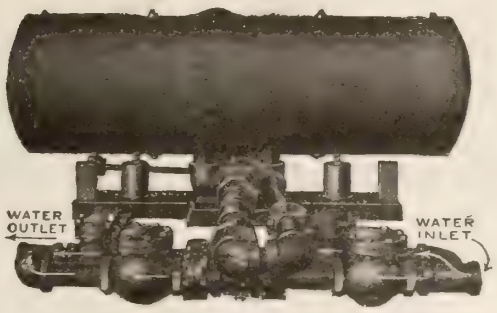
Farnsworth-equipped plants produce more steam with less fuel and less expense than other plants. Thousands of dollars are being saved by the Farnsworth System, not alone in Canada and United States, but in all countries of the world, wherever steam is used for heating or manufacturing process work—its value is thoroughly proven!

When the amount of expense saved by Farnsworth equipment is taken into consideration the question of installation costs is eliminated. It quickly pays for itself. It is a safe and profitable investment. Experience proves that in the majority of cases only three to six months' operation is required to return first costs.

These are facts. Plant owners have nothing to lose and everything to gain by investigating the Farnsworth System and the engineering staff of The Canadian Farnsworth Co. will be glad to advise and co-operate with them in solving steam line drainage and boiler feeding.

The Farnsworth Automatic Duplex Boiler Feeder

The "Farnsworth" should not be confused with ordinary steam traps. It is a machine built for Boiler Feeding. Note the cushioned dashpots, a feature which provides against shocks and ensures smooth operation.



The Sign of Coal Saving

No leaky steam valves with the Farnsworth in your plant; no constant waste of steam to the outside air; no springs to loose their tension; no levers to jump out of place; no weights to cause poundings, and no trunnions to bind and stick, or leak water and steam.

The Duplex feature of construction ensures a continuous flow of feed water to the boiler. Then, the machine being always equalized with the boiler provides against sudden shock or jar in the feed lines. There is no hold-up on the return lines as is the case with ordinary return traps, as the feeder is constantly receiving the water.

Our expert steam and condensation engineers are at your service. Have them investigate and make reports.

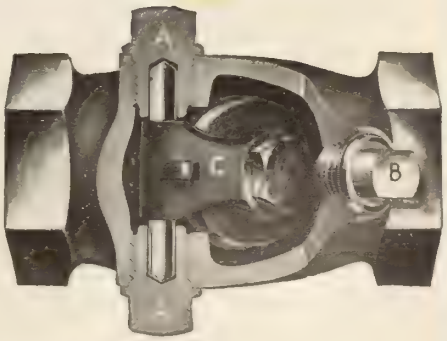
SWING CHECK VALVES

External View

Registered and approved for 200 lbs. steam pressure



Sectional Top View

"BUILT FOR SERVICE"

Note the correct angle at which the disc rests when closed. Prevents opening of same from pressure of condensed water in pipe, or from pipe line getting out of true. The body of the valve proper is not subject to wear from action of disc, as the hinge pin "C" bears on the two end plugs "A," and these parts can be renewed at very little cost. In some makes of valves the hinge "C" rides in a groove of the body proper and in case wear throws the disc out of line, the whole valve has to be replaced.

The double plug construction enables the valve, if installed in a wall pipe, to be taken apart without taking down the pipe line, as one plug is always accessible. The valve can be reground in a very few minutes, making same as good as new. The metal is of excellent quality and is distributed evenly and liberally throughout body and diaphragm to insure strength.

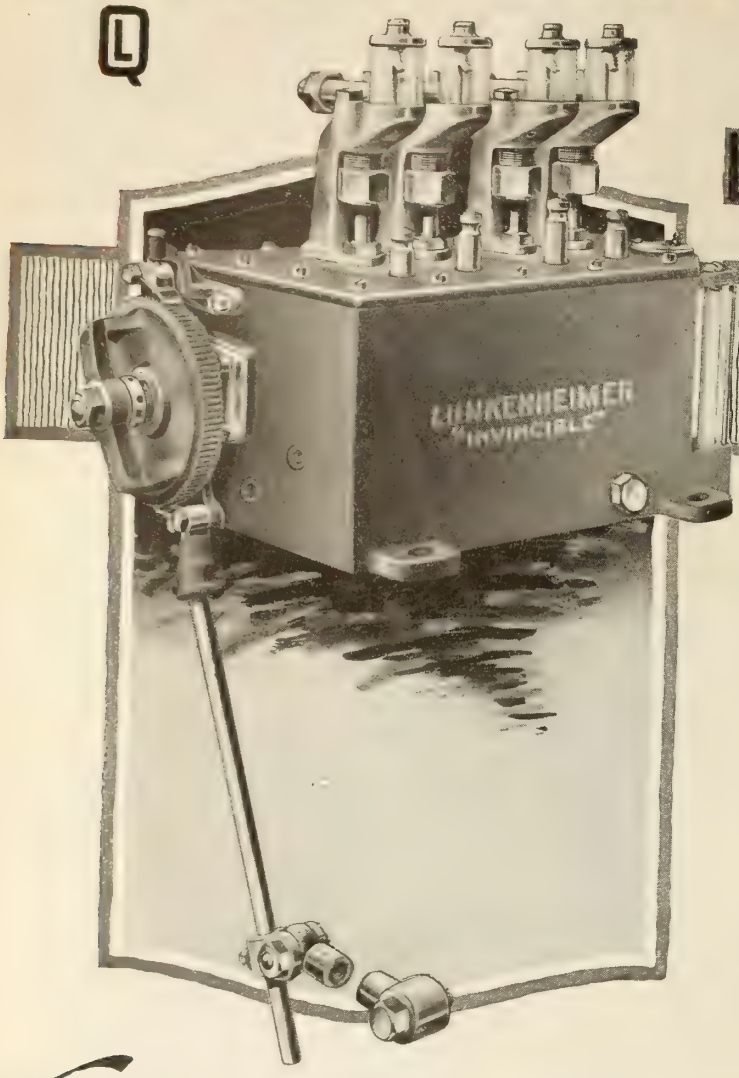
LUNKENHEIMER

CYLINDER LUBRICATORS



AMERICA'S BEST
LUNKENHEIMER
"QUALITY"
SINCE 1862

For Steam and Oil Engine, Pump and Air Compressor Cylinders

Dependable lubrication,—the delivery of the proper quantity of oil to the cylinders—is assured when power units are equipped with Lunkenheimer Cylinder Lubricators. They are positive in operation, delivering uniformly until reservoir is empty the exact quantity of oil for which the feed is set.

The feed regulation permits of close adjustment, the oil drops form perfectly and are clearly visible in the large sight-feeds. Lunkenheimer Cylinder Lubricators are made in a variety of types, including Hydrostatic, Hand and Mechanically operated,—practical in design, and durable because of the high quality materials used. All the parts are interchangeable and can be renewed should necessity require.

Equip with "LUNKENHEIMER" CYLINDER LUBRICATORS and satisfactory service is assured.

Write for descriptive booklets No. 526—DC. and 572—DC.

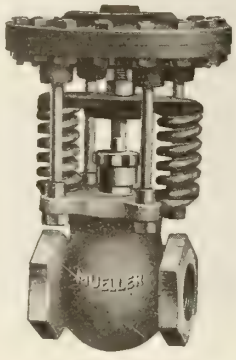
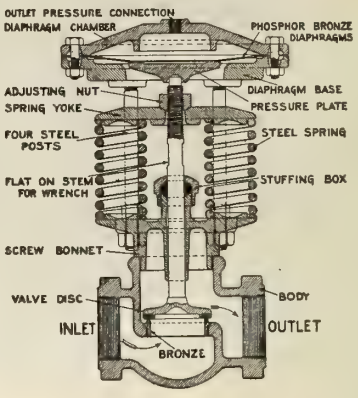
MUELLER

Reducing and Regulating Valve and Pump Governor

For Steam and Oil; Single Seat; Direct Operated



No. A5120
Code—*Ranchero*



This valve is for protection against abnormal rises in initial pressure and where a reasonable variation in the delivery pressure is not objectionable.

For pump governors, power purposes and blower engines it is unexcelled.

It operates most efficiently where the initial pressure is constant and the required reduction is not too great.

Regulators of this description are suitable for pressures up to 150 pounds. For pressures in excess of 150 pounds, submit specifications.

WE MAKE MUELLER

Basin and Bath Trimmings, Bibbs, Sill Cocks, Ferrules, Curb or Service Cocks, Corporation Cocks, Tapping Machines for Water and Gas, Service Clamps; Regulators and Reducing Valves for Water, Air, Steam and Oil; Bubbling Fountains, Gas Cocks, Globe, Angle and Check Valves, Etc. Forgings in Brass; Castings in Brass, Bronze and Aluminum; Specialties for Automobile Companies, including Bronze Bushings, Gasoline Cocks, Etc.

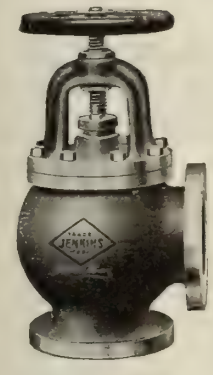
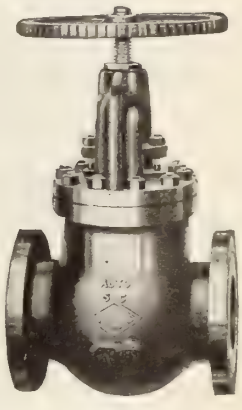
JENKINS VALVES

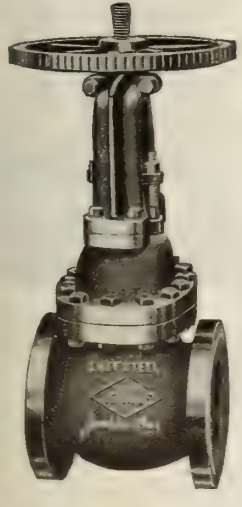
TRADE JENKINS MARK





Jenkins Bros.

Built With a High Safety Factor



Jenkins Valves are carefully constructed to withstand excessive strains at particular points—and then some! To stand up under the greatest strain to which they may be subjected is not enough—a high safety factor must maintain the Jenkins reputation.

Scientifically Selected Metals

Jenkins Valves are made of metals scientifically chosen to balance the varying temperature to which valves may be subjected or — as with manganese bronze and monel metal spindles, to withstand corrosion.

Correct design, scientifically chosen metals and careful construction—these are the reasons why you can depend on Jenkins Valves for reliable service.

New Truths and Old Fallacies

Fusibility of Alloys—*Continued*

Alloys are solutions of one metal into another and the degree of solubility varies.

The term "fusible metals" is usually applied to alloys whose melting point is below that of tin. The lowest freezing point in a series of alloys was first designated by Doctor Guthrie as an Eutectic. The eutectic structure is defined as being composed of the different constituents in juxtaposition. There is a natural limit of saturation in a solid compound, just as there is in a liquid compound, and when that limit is reached the undissolved portion separates and falls out, as it were, into the matrix or eutectic and at that point occurs the lowest freezing point or eutectic, which is also the lowest melting point.

In an alloy composed of lead and antimony, 13 per cent. of antimony is the natural limit of saturation and any antimony in alloy in excess of 13 per cent. can be easily seen in the eutectic compound under moderate magnification in the form of crystals, but the antimony dissolved in the eutectic compound is so intimately mixed and finely divided that the highest magnification is required for its resolution. As the undissolved antimony crystals multiply and become attached to one another, forming bridges, the alloy becomes increasingly brittle to the extent of the antimony used in excess of 13 per cent.

The fusing point of an alloy is always less than the mean of its constituent metals and the fusing point of trianary or quaternary alloys containing, respectively, three and four elements, are lower than a binary alloy. The molecules of different elements combined are supposed to be in constant motion in effort to adjust their crystalline structures, which likely accounts for alloys having lower fusibility than the single metals of which they are composed.

Continued next month.

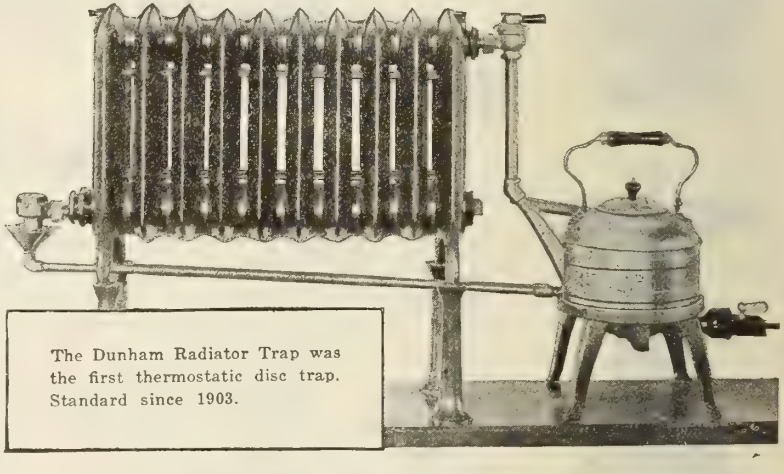
Heating a radiator with a teakettle

It was done at the Ottawa Technical School before a group of engineers who were amazed at the demonstration. It proved beyond question that low pressure steam will quickly heat a radiator to 100% efficiency if the trap is right. It undisputably proved that the Dunham Radiator Trap functions perfectly.

Since 1903, the Dunham Radiator Trap has been eliminating any chance of trap trouble in thousands of installations. It was the first thermostatic disc trap. Think of this when you think of traps, and remember that the Dunham Trap is only one element in Dunham Heating Service. The entire service offers much to the man who plans, sells and installs the heating system—and more to him who pays the bills.

If you welcome suggestions that do not obligate you, get in touch with our nearest office. For authoritative information, write for booklet, "Data on Dunham Heating."



The Dunham Radiator Trap was the first thermostatic disc trap. Standard since 1903.

Firing that is Different

WITH the RILEY STOKER the coal is fed—the fire cleaned—the ash discharged, *continuously* and *automatically*. All done without waste or effort, efficiently and economically.

It is not only the things the RILEY STOKER does but the way it does them. For instance, when steam is wanted quickly and time is precious, you can get this steam instantly and economically by increasing the motion of the grates.

With the first turn of the cranks the grates start moving—the whole fuel bed is thrown into action. There is no watching nor waiting—poking nor slicing—the stoker responds instantly and in two or three minutes the boiler will be operating at 200 or 250% of rating.

It is this kind of flexibility that saves not only for the central station but for the industrial plant.

Riley Stoker Catalog HR-5 sent on request

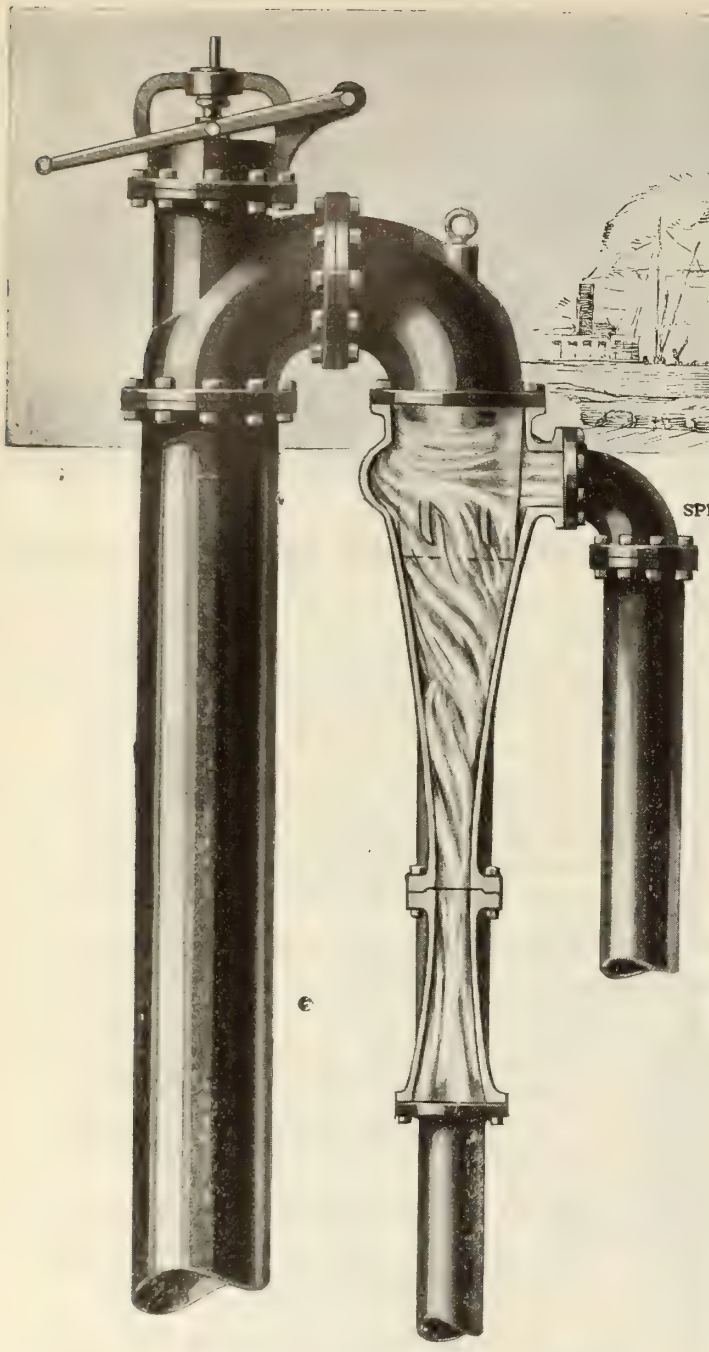
SPIROJECTOR CONDENSER



Utility and Economy are both served by Worthington

FOR installations of condensing machinery where first costs, economical maintenance and efficient performance are equally vital, Worthington Spirojector Condenser enjoys great favor.

Worthington Spirojector is of the syphon type with particular Worthington construction features that assure steady, perfect vacuum without aid of vacuum or dry-air pump. Air and non-condensable vapors are entrained and carried out by the falling water which is injected at opening below elbow in exhaust pipe and discharges as a rapidly descending spiral current of water.

Worthington builds all types of condensing machinery and since 1840 has developed a service and organization which is world-wide. Engineering service is freely tendered and carries with it no obligation to you.

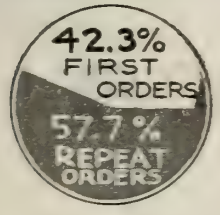
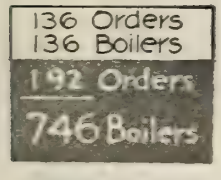
420,500 hp. BOILERS EQUIPPED in JAN.-FEB., 1920

Industrial America Says "Yes!"

When, in a period of sixty days, Industrial America orders Diamond Soot Blowers to equip the enormous total of 420,500 H. P. of boilers—the event is of national importance. It seems probable that never before in the history of power equipment has a single make of boiler room apparatus of any type for any service, been ordered or applied to as many boilers. What is the secret behind this tremendous vote of confidence? Is it to be found in a record of 18 years of genuine service—during which Diamond Soot Blowers have saved millions of tons of coal and millions of dollars in labor—and have stood up and performed their functions satisfactorily under the hardest operating conditions, justly earning a reputation as ***"the best paying investment in the power plant?"*** Industrial America says "Yes!"





Tremendous Horsepower Involved: Measured in central stations, the boilers equipped with Diamond Soot Blowers in January and February are equivalent to twenty large Edison plants. They are as powerful as harnessed Niagara. It would take a train of flat cars eight miles long to hold them.

25 Makes of Boilers Equipped: A total of 328 orders to equip 932 boilers and economizers was received. These included 23 different makes of water tube boilers, to say nothing of fire tube boilers and economizers. Among prominent makes were B.&W, Badenhausen, Bigelow-Hornsby, Casey Hedges, Connolly, Edgemoor, Erie City, Heine, Keeler, Kidwell, Stirling, Union, Wickes, etc.

57.7 Per Cent Repeat Orders: Of the 328 orders received, only 139, or 42.3% were first orders. The remaining 57.7% were repeat orders. Note the records of a few representative concerns.

Penna. Utilities Co. . .	9th order
Ford Motor Co. . . .	11th "
Texas Co.	11th "
Inland Steel Co. . . .	11th order
Cent. Illinois Pub. Ser. .	12th "
W. Va. Pulp & Paper Co.	14th "
Standard Oil Co. . . .	16th "
Brooklyn Edison Co. .	16th "
Armour & Co.	16th "
General Electric Co. . .	27th "

Two-Thirds of Orders Cover Two or More Boilers: Of a total of 328 orders to equip 932 boilers, 136 orders covered one boiler each, and 192 orders covered 796 boilers—an average of four each. Here are some typical orders:

Minnesota Steel Co. . .	11 Boilers
Standard Oil Co. . . .	12 "
Brooklyn Rapid Transit .	18 "
Minn. & Mt. Power Co. .	24 "
Naragansett Elec. Co. .	28 "
Great Northern Paper .	30 "
Proctor & Gamble . .	50 "
W. Va. Pulp & Paper Co.	23 Economizers

The savings in fuel and labor, and the increased boiler efficiency effected by Diamond Soot Blowers are directly responsible for these orders. If your boilers are not equipped, you owe it to yourself to write for full information.

How do you buy a steam trap?

DO you look for simple, sturdy construction? Sure you do—the simpler the better—because that means fewer, easier repairs, if any.

Do you look for steady, reliable, uncomplicated operation? Of course—if it doesn't work you don't want it.

Do you look for a good record of results accomplished for other users? Certainly—you want a trap with a good reputation—one in which others feel confidence.

All right; now here's the Johns-Manville Steam Trap, the simplest Steam Trap made—and unequalled for rugged strength. It operates continuously and faithfully—without any fussy mechanism to get out of order. And thousands in satisfactory service bear witness to its good repute.

How it works

It's a hollow copper ball that does the work. As water flows into the trap, the ball rolls up, exposing the outlet, and water is discharged. Any air that may be present is also drawn off. But when the water level falls, the ball rolls down with it and steam cannot pass the trap.

Saving Time and Money

Nonpareil Corkboard Insulation is manufactured in three separate factories—two on this side of the Atlantic Ocean and one on the other—and is stocked in warehouses located in many of the principal cities of the United States and Canada.

Such extensive manufacturing and distributing facilities afford significant advantages to the buyer of insulation—particularly in these days of crippled transportation systems. They make possible shorter railroad hauls, quicker deliveries, and a substantial saving in freight charges on less than carload shipments.

Top—Factory at Camden, N.J.
Centre—Factory at Beaver Falls, Pa.
Bottom—Factory at Seville, Spain.

The merits and various uses of Nonpareil Corkboard are explained clearly in the 152-page illustrated book, "Nonpareil Corkboard Insulation." Send for a copy to-day--it will cost you nothing.

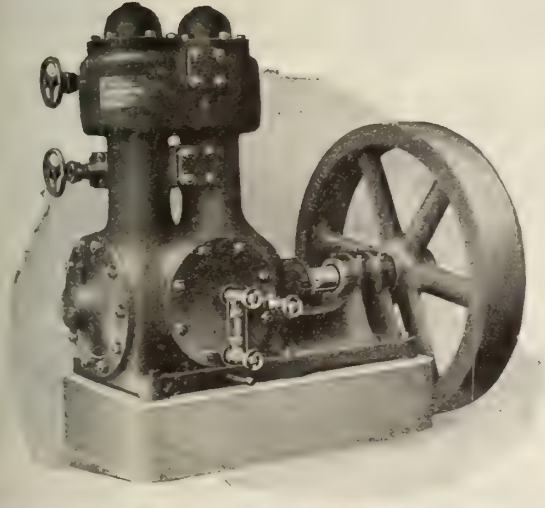
ARMSTRONG CORK & INSULATION COMPANY 504 McGill Building., Montreal, Quebec.

Also manufacturers of Nonpareil Cork Covering for cold pipes; Nonpareil High Pressure Covering for steam lines: Nonpareil Insulating Brick for boiler settings, etc.; Nonpareil Cork Machinery Isolation for deadening the noise of machines; Circle A Cork Brick for cold storage room floors; and Linotile for floors in offices, residences, etc.

Nonpareil Corkboard Insulation

For All Cold Storage Rooms

Mechanical Refrigeration



Reliable--Beneficial

THE many benefits common to all users of MECHANICAL REFRIGERATION, should make it a valuable adjunct to **your** business.

The uniform temperatures it provides have a better holding effect on the product in storage than ice, because the temperature produced by ice is not uniform, varying with the amount of ice in the refrigerator.

MECHANICAL REFRIGERATION permits the maintenance at all times of any temperature desired in the refrigerators or cold storage rooms, whereas you can not always get ice just when you need it, and a delay of a few hours often means a loss through deterioration of the product in storage.

If interested in MECHANICAL REFRIGERATION, a request for information and prices will receive our prompt attention.

A Boiler Plant where–

Engineering practice in boiler building has seen many changes in the last 35 years. We have been through them all. Our shop is fully abreast of the times—and we have a few exclusive "betterments" that we have worked out for ourselves. But we have never yet found any idea to beat the one we started with—to build every Boiler so well, so "whole-heartedly" if you will, that it will be certain to sell at least one more for us. We may not be able to suit everybody, but our work assuredly appeals to the man who wants THE BEST.

REES RoTURBo

Rotary Jet Condensers and Vacuum PUMPS

Sole Canadian Manufacturers

The REES-RoTURBo products are widely used in Great Britain and United States and are recognized as the very latest development in this class of apparatus, which include REES-RoTURBo Patent Pressure Chamber Self-Regulating Pumps, Rotary Jet Condensers and Rotary Vacuum Air Pumps.

The Rotary Jet Condenser is used in connection with steam turbines and reciprocating engines. It is particularly adaptable to sugar and salt boiling plants, etc. The Rotary High Vacuum Air Pump is identical in principle with the Jet Condenser and possesses similar advantages. **Made in Canada by the G. & McC. Co. only.**

The engineering profession of Canada is well acquainted with the **quality** in construction that typifies all G. & McC. Co. products —this **quality** is thoroughly maintained in REES-RoTURBo Rotary Jet Condensers and Vacuum Pumps.

A Paper on Modern Boiler Practice

The Following Paper Read Before the Engineering Institute of Canada Gives a Very Complete Account of the Trend in Modern Boiler Design and the Economies Effected Thereby

By F. A. Combe, A.M.E.I.C., Consulting Engineer

THE object of this paper is to give a brief outline of the principles governing boiler and furnace design, with a review of our present knowledge of the laws related thereto, and the trend of modern practice, together with some general notes regarding boiler installation and operation which may be of interest to Canadian engineers and possibly timely in view of the number of new steam plants and extensions to existing plants which it is expected will be undertaken in this country, now that war restrictions have been withdrawn.

During the last eight years there has been a considerable advance in the art of generating steam, following a better understanding of the combustion of fuel and heat transmission in boilers, which, while not leading to any radical change in actual construction, has resulted in improved arrangement of boiler heating surface, with more efficient furnaces, boiler settings and plant operation, and engineers and plant owners are beginning to pay more attention to this very important part of power production.

In the past it has been too often thought that anyone could lay out a boiler room, with the result that plants have been put in without proper consideration of their suitability for the particular conditions, or, even when good boilers, stokers and main apparatus were installed, no facilities for economic operation were provided. More money can be saved or lost in the boiler room than in any other part of the plant, yet, while the latest refinements may have been added to the engine room and electrical side, the boiler room has been considered as a necessarily dirty place to be avoided as much as possible. The condition of this same boiler room under operation is, however, usually a direct indication of the ability of the plant designer or management, or both, as a boiler room need not be dirty, and dirt generally means inefficiency and bad management somewhere. At the present time when the question of fuel supply is of such importance in Canada, every effort should be made to ensure its efficient use, and steps taken where possible, through education and control, to cut down the enormous waste which occurs annually through inefficient operation, or the

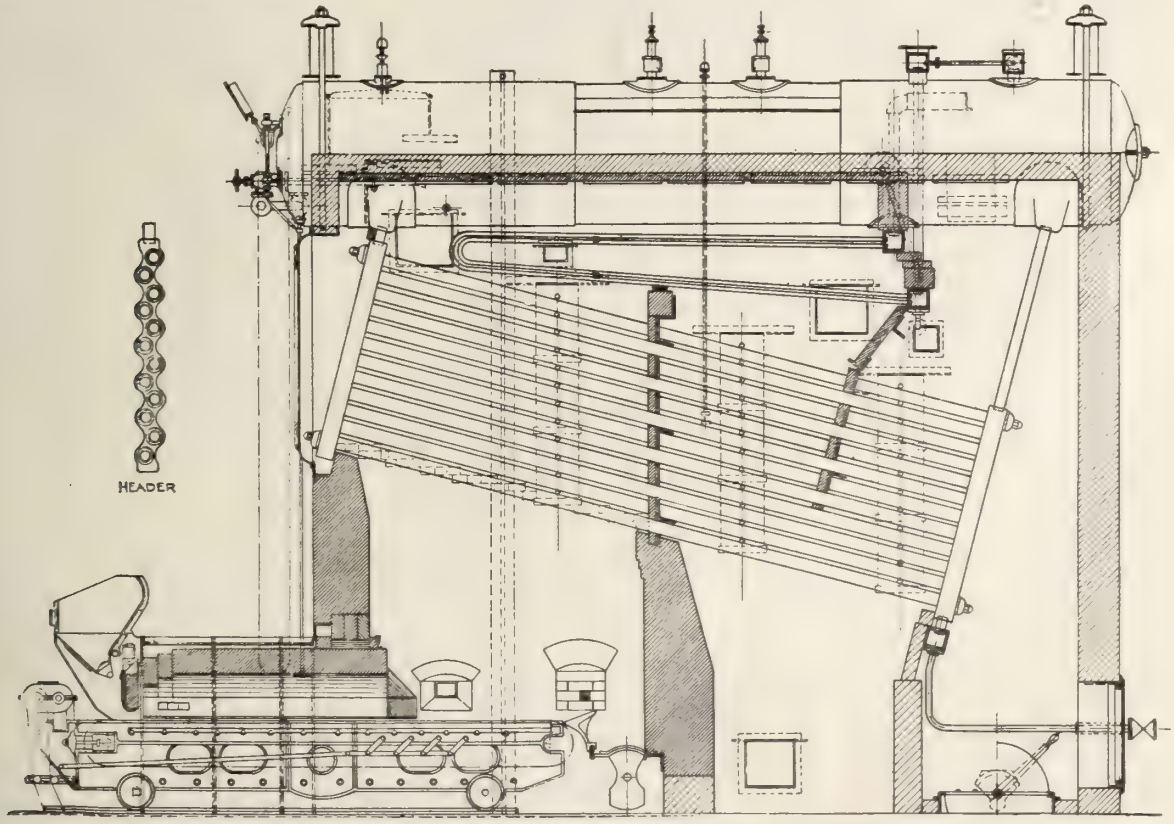

FIG. 1—STANDARD LONGITUDINAL DRUM SECTIONAL HEADER BOILER.

false economy or indifference of the plant management.

The operating efficiency of the engine room machinery is largely inherent in the design, that is to say, beyond the control of the attendant, but, although a boiler and furnace must be properly designed, its actual efficiency in service is, to a great extent, dependent upon intelligent operation and supervision, and for that reason warrants the placing of the most intelligent and highest priced men with every modern appliance in this part of the plant, since an increase of even a fraction of one per cent. in efficiency represents the saving of a considerable quantity of coal annually. Such a distribution of labor and superintendence is very seldom the case at the present time.

The present day tendency towards high steam pressures and temperatures, concentration of power and larger unit capacities have led to the practical elimination of the shell boiler for this service and to certain modifications in the setting and rating of water tube boilers. The different water-tube boilers made to-day, suitable for these conditions, resolve themselves into two general classes horizontally inclined straight tube boilers and vertically inclined bent tube boilers. Fig. 1 shows a section of a standard longitudinal drum boiler of sectional header construction with vertical baffles, fitted with a superheater and chain grate stoker, having a high furnace setting; and Fig. 2 shows a large double setting vertically inclined tube boiler with superheater and underfeed stokers. For the purpose of illustrating the application of the principles entering into boiler design, the author will confine his attention chiefly to the former type of boiler and its recent development.

The peculiar conditions under which boilers must necessarily work affect their design to a greater etxent than with most machines. It is possible to design a boiler which would give a higher efficiency under test conditions than any yet built, but taking into consideration the general class of service, attention, ease of cleaning, first cost and maintenance, a compromise must be made for continued satisfactory and efficient service.

The more severe demands of modern service and a better realization by engineers of the possible economies to be effected in the boiler room has been encouraging the development of boilers for higher efficiency and rating, but it must be understood that, as with any other machine, the higher the rate at which a boiler is operated the more careful attention is needed and the less abuse it will stand. Boilers, engines, or anything else can be, and are, built to stand rough usage, but, if the highest efficiency and rating be desired, they must be treated with respect and for the purpose for which they are designed, for instance:

The function of a boiler is to make steam and it is not at any time the proper place for the treatment and deposit of the impurities in the feed water. Boilers designed for, and operating under, moderate loads will stand a lot of abuse in this way, albeit at a loss in efficiency, and under such conditions the use of chemicals or boiler compounds fed into the boiler with the feed water may be justifiable to lessen adherent scale, but pure soft water must be used in any type of boiler which is to be operated at high rates of evaporation in order to get proper benefit from the installation, and to avoid tube troubles, and this usually necessitates the provision of an independent water purifying plant for the raw make up water in the feed supply.

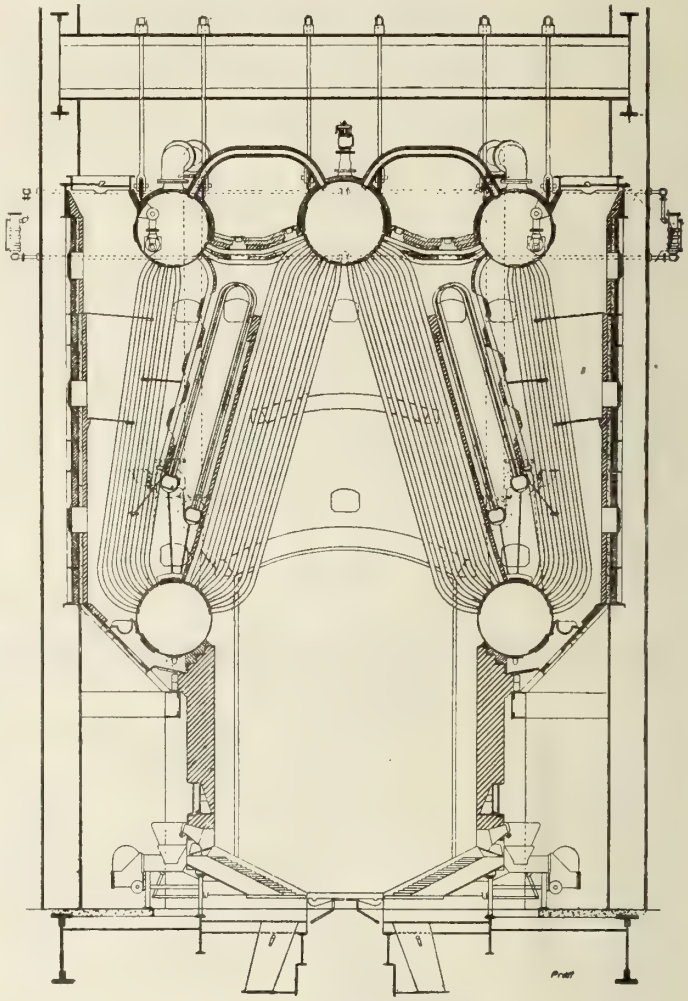

FIG. 2—DOUBLE SETTING STIRLING BOILER.

Rating and Capacity

When speaking of boiler loads or high and low rates of evaporation of boilers, it is necessary to have a clear understanding of the unit on which such evaporations are based, that is, what constitutes a normal full load? In Europe and other countries boilers are usually rated on the quantity of water which they are capable of evaporating per hour under certain conditions with a specified heating surface, but in Canada, following the custom of the United States, boilers are generally rated simply in boiler horsepower, a term often very loosely used.

A boiler horsepower, in its true sense, is solely a unit of evaporation, being equal to 34.5 lbs. of water evaporated per hour from and at 212°F. and equivalent to the standard adopted by the boiler committee of the Centennial Exposition in Philadelphia in 1876. The term has nothing to do, strictly speaking, with the heating surface of the boiler, but at different stages of progress of the art, manufacturers of stationary boilers have adopted as arbitrary standards, certain amounts of boiler heating surface which could be taken as suitable for economically evaporating one boiler horsepower under average conditions of service and with a definite ratio of heating to grate surface. In recent years 10 square feet of heating surface per boiler horsepower or the equivalent of approximately 3½ lbs. evaporation per square foot heating surface has been considered a nominal full load rating for a water tube boiler of standard construction, but considerably higher rates are adopted in modern stationary boilers designed for high duty service, as also in marine boilers where average evaporative rates of 6 lbs. and over per square foot heating surface are usual.

The normal rating, or rate of evaporation, of a boiler, and its point of maximum efficiency is entirely dependent on the design, and while higher rates than 3½ lbs. per square foot heating surface per boiler may constitute a so-called overload on a boiler designed for 10 square feet heating surface per boiler horse-

power, with a ratio of heating surface to grate area of about 50 to 1, and the efficiency may drop with such overload, it does not follow that the same condition will exist with a boiler and furnace designed for a different rating.

The rate of conductivity of the metal of the heating surface is sufficiently high to carry away considerably more heat than can possibly be transmitted in boiler service without danger of burning, provided that water be in contact with the one side of the metal, so the limit of capacity alone is practically only governed by the positive circulation of the water in the boiler, the cleanliness of the heating surface, inside and out, and the amount of fuel that can be burned, or the gases which can be passed through the boiler.

There is very little difference in temperature of the water throughout any part of a well designed water tube boiler, the circulation being caused by a pumping action set up by the steam bubbles, in a similar manner to an air lift pump, either in the front tubes of a vertically inclined tube boiler, or in the uptake headers of a sectional horizontally inclined tube boiler, and, as with an air lift pump, the rapidity and efficiency of the pumping action is dependent on the avoidance of large chambers in the water passages in which eddies and down currents impede the pumping action. Tests recently carried out on a horizontally inclined tube boiler of the header construction, 28 tubes high, showed that this pumping action amounted to the equivalent of some 18 inches of water head when the boiler was operating at rated capacity and that it increased progressively as the load increased. Boilers similar to that shown in Fig. 1, equipped with a duplex furnace are in service operating up to 400 per cent. rating during peak load periods or an average evaporative rate of 14 lbs. per square foot heating surface when using purified feed water, so that as far as capacity alone is concerned, a boiler having good circulation can be run at considerably higher rates than has been the usual practice, provided it be kept clean. Cleanliness and positive rapid circulation become of increasing importance as the rate of evaporation is increased.

In order to better appreciate the significance of evaporative rates, let us examine the mode of heat transfer in a boiler in the light of our present knowledge, and at the same time see how the general principles are applied in modern boiler design.

Assuming coal to be burned under a water tube boiler at an efficiency equivalent to the production of 12,500 B.t.u. per pound with 18 pounds of gaseous products of combustion; then the temperature above the surface of the fuel bed would theoretically be approximately 3800 deg. The heat is transmitted to the boiler heating surface by direct radiation from the surface of the fuel bed and furnace walls and by convection from the hot gases passing over the tubes.

Radiation

The amount of heat absorbed by the surface of the tubes directly exposed to radiant heat from the furnace is generally proportional to the difference of the fourth powers of the two surfaces, or $= C(T^4-t^4)$ where C is a constant for any unit of surface and time. The laws governing radiant heat or heat rays are analogous to those for light, the heat transfer being extremely rapid, but the great proportion of the heat energy is supplied by the obscure or dark rays, only a very small amount being carried by the actual light or visible rays.

The value of the coefficient in the above radiation formula was determined experimentally for black surfaces by Stefan about 30 years ago, and while this coefficient has been taken as applicable to the partly sooted surfaces in a boiler furnace it is probably far from gases in the furnace to heat rays, their capability of radiating heat themselves, the reflecting and absorbing power of the fire brick furnace walls and the proper consideration of the exposed areas, are all points on which there is little authoritative data, although investigations are being made into this subject at the present time. Of course a close determination can never be made if the area of the hot surface of the fuel bed is to be a determining factor, as it is obviously impossible to do more than very roughly estimate the average extent of the irregular surface, and there will be, in addition, radiation from the incandescent carbon particles in the gases; but it is questionable if this surface is a necessary factor. With gaseous or oil fuel, we have to deal with volume radiation which presents a somewhat similar case to that in a gas engine cylinder where the heat from the explosive charge is transmitted to the water jacketed cylinder walls chiefly by radiation, as brought out in investigations undertaken by the explosives committee of the engineering section of the British Association some years ago.

One thing we do know is that in a Babcock and Wilcox boiler, the amount of water evaporated per hour per square foot of surface of the lower rows of tubes exposed to furnace radiation, with a furnace temperature around 2,500 deg. F. is at least from 50 to 65 lbs., and as this may represent over one-half the total evaporation of the boiler at normal rating, the importance of a full knowledge of the subject of radiation is evident, while it incidentally shows how high the evaporative capacity of a tube is, and that an average evaporation rate of 3½ lbs. per square foot heating surface for the whole boiler gives no indication of the amount of work which any part of the heating surface is doing.

Failure to take into consideration the extent of heat radiation often leads to considerable error in boiler work, both in testing and recording and also in details of the boiler and furnace setting. For instance, it is extremely difficult, in fact impossible with the usual type of instruments procurable, to measure exactly the temperature of the gases in a boiler setting owing to radiation from the thermometer bulb or end of pyrometer element to the hot furnace or to the cooler boiler heating surface in close proximity. H. Kreisinger, of the U. S. Bureau of Mines, Washington, presented a paper to the American Society of Mechanical Engineers, in 1917, dealing with this subject, in which he gave the probable error, arrived at by experiment, in temperature measured by a thermo-couple placed amongst the tubes of a water tube boiler as from approximately 600 deg. too low at 2,000 deg. F. to 40 deg. too low at 500 deg. F. when using a common form of pyrometer with a ½ in. diameter element; also showing that the error was proportional to the size or exposed area of the instrument. The author has had some success with a special cap screen surrounding the end of the instrument element, that is, measuring success by the higher temperature recorded, but in any case there will be some correction to make. Even the measurement of the temperature of the flue gases leaving the boiler setting is liable to considerable error unless proper precautions are taken.

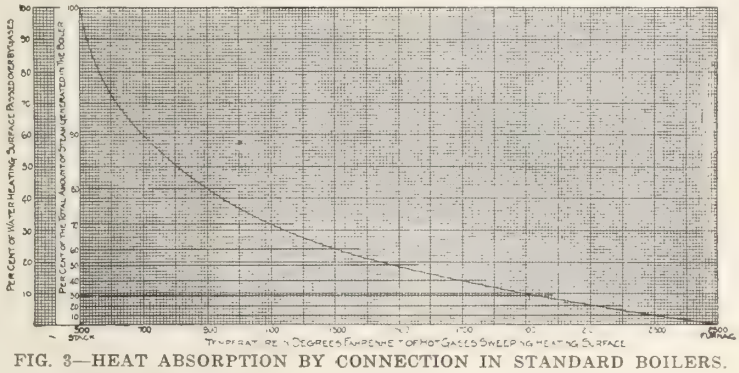

FIG. 3—HEAT ABSORPTION BY CONNECTION IN STANDARD BOILERS.

Again, the opinion was held until recently that an air space in the walls of a boiler formed a good heat insulator. Actually, it is useless and even a disadvantage, as, although still air is a poor conductor of heat, the rate of conduction is proportional only to the actual difference of temperature of the surfaces, whereas radiant heat will pass across the

air space at a rate proportional to the difference of the two surfaces. For low temperatures, as in refrigeration work, air spaces are beneficial, but with a high temperature difference, the heat transfer becomes very great.

To obtain a better insulated wall than that of ordinary red brick for a boiler setting, special insulating material is to-day often used, either as a middle course between the firebrick lining and the outer wall facing, or on the outside of the brick wall, but it should be realized that if too good an insulation is made, it becomes increasingly difficult with certain types of furnaces to get a firebrick lining to stand the higher temperature attained. Sometimes the entire boiler brick setting is enclosed in a steel casing, but this is rather to give a tight seal preventing the infiltration of air, which occurs through any ordinary brick wall, especially in boilers operated at high ratings with a corresponding greater draft suction in the setting. The cost of these castings is high, but, if properly constructed, are of considerable value and in many cases are undoubtedly a good investment. If they are used, there should always be a course of asbestos or other insulating material between the brickwork and the casing, otherwise the radiation loss may be increased owing to the metal presenting a beter radiating surface than the brickwork.

Furnace Duty

Returning to the furnace and the assumed case, it will be seen that, with the same efficiency of combustion maintained, since heat will be radiated as quickly as generated, the actual apparent temperature will not reach the theoretical figure of 2,800 deg. until sufficient coal is being burned to generate the heat necessary to satisfy the radiation equation for 2,800 deg. in addition to raising the temperature of the products of combustion to a figure dependent upon their rate of liberation. The stage when this condition is reached will depend on the area of the cool surface exposed to radiation and it does not necessarily mean that apparent high furnace temperature is essential to high efficiency, although they will coincide to an extent dependent upon the constituents of the fuel.

In brick lined extension furnaces or when the lower row of boiler tubes over the fire are encased in brick tiles, as for certain forms of baffling, higher temperatures are attained at a low rate of combustion on the grate, but this means that the gases also enter the bank of tubes at a higher temperature for the same load, resulting in a corresponding higher exit gas temperature and consequently reduced efficiency, while the higher furnace temperature shortens the life of the furnace brickwork.

With such a horizontal baffling, there will, of course, be radiation from the furnace or hot brickwork to the exposed tubes of the gas passage beyond the tiles, while heat will be conveyed from the furnace to the lower tubes through the encircling tiles by conduction and possibly secondary radiation, but following the fourth power law of temperature difference the amount will be considerably less than for a direct exposure, and it is, therefore, preferable, wherever a high furnace temperature is not necessary for proper combustion, for a lower horizontal baffle to take the form of flat tiles laid on the second row of tubes from the bottom so as to gain the full effect of direct radiation, which is the most active, and, therefore, the most economical mode of heat transfer.

If the furnace efficiency could be maintained constant, the temperature of the gases entering and leaving the boiler heating surface would increase with increasing coal consumption, resulting in a continued decrease in overall efficiency as the load increased, but in general practice, the furnace and grate efficiency increases with the load up to a certain point dependent on the proportions of boiler, furnace and grate, so offsetting the drop in efficiency due to the higher flue gas temperature. With a standard setting of boiler designed for 10 square feet of heating surface per boiler horsepower, or an equivalent normal full load evaporation of 3½ lbs. per square foot heating surface, and a ratio of heating surface to grate of about 50 to 1, the maximum efficiency will usually be maintained fairly constant from 90 per cent. to 130 per cent. rating. Below 90 per cent. rating the loss in efficiency is chiefly due to incomplete combustion in the furnace and grate and above 130 per cent. rating chiefly due to the increasing exit gas temperatures, the furnace and grate having then reached their highest efficiency. For other proportions and designs of boiler and furnace the point of maximum efficiency will be different; (for instance, the very complete tests carried out on the large Stidling boilers at the Detroit Edison Company's plant some years ago showed the highest normal evaporation rate) and dropping in a straight line to 76 per cent. efficiency at 200 per cent. rating. This remarkably high efficiency over such a wide range of load was due to the exceptionally large combustion chamber, promoting almost complete combustion even at low loads; the skilled regulation and operation; and the small proportional radiation loss from the walls with such a large unit. Fig. 2 shows a section of one of these boilers.

FIG. 4—HEAT TRANSFER IN BOILER TUBES.

The general tendency in modern design is to provide greater and greater furnace volume to ensure more complete combustion before the gases reach the comparatively cool boiler heating surface. Not many years ago the ratio of cubic feet of furnace volume to square foot of grate usually provided was about 3 or 3½ to 1, whereas to-day we may have 5½ or 6½ to 1 for natural draft stokers and even more for forced draft

stokers, particularly when high overloads are demanded. In the Detroit Edison boilers mentioned above the ratio was approximately 9 to 1. For horizontally inclined tube boilers this increased combustion space generally means that the mean height from the floor line to the lower tubes over the fire has been increased from approximately 6 or 7 feet to 9 or 10 feet and over, where conditions permit, and as required by the nature and volatile content of the coal, type of stoker and duty.

Convection

The best method of passing the gases over the tubes, and the relative advantage of different form of baffling have been discussed at various times, but it seems reasonable that a cross flow over several passes of staggered tubes avoids stratification by ensuring the most thorough breaking up of the gas currents, with the consequently better contact of all particles with the walls of the tubes, while with the first pass at the upper end of the tubes, a contra flow action to the circulation of the water in the boiler is obtained, and, at the same time, with a horizontally inclined tube boiler, the circulation will be improved, and the danger of blistering the lower row of tubes lessened by procuring the quick release from the tubes of the steam bubbles formed.

The laws governing heat transfer by convection from the gases passing over the boiler heating surface has been the subject of many investigations, and formulae have been put forward based on mathematical deduction and laboratory experiment, but the great majority of these formulae, while holding good within the limits of the experiments, are not applicable without considerable correction for the conditions existing in a full size commercial boiler, especially where the gases pass across a bank of tubes, in which case the area of the gas passage is not constant. In view of the lack of authoritative data on the subject, the Babcock & Wilcox Company, a few years ago, conducted a series of experiments with a specially constructed plant to determine a formulae with coefficients which could be depended upon, for the rate of heat transfer in boilers.

The relation of the heat absorbed by convection only from the gases to the amount of heating surface passed over in a boiler of standard proportions under coal fired conditions on the basis of 10 square feet heating surface per boiler horsepower is given by the curve, Fig. 3, which shows that the great proportion of the total evaporation takes place in the first pass of the boiler and very little in the last pass; for this reason it does not pay, with these proportions, to increase the heating surface by adding another pass.

A test was published a few years ago of a 4 pass boiler in which the actual drop in temperature through the last pass was only 67 deg. and even this drop was obtained only by reason of the low steam pressure carried (117 lbs. per sq. in.). With a steam pressure of 200 lbs. and a corresponding less difference of temperature between the gases and the water, the flue gas temperature must have been higher and the value of the fourth pass still further reduced.

Waste Heat Boilers

In direct fired boilers where furnace temperatures are high, and the weight of gas per boiler horsepower comparatively low, there is not a great deal of difference in heat transfer between several different types of standard boilers, fire tube or water tube, when new and clean; but with boilers arranged to utilize the heat from waste gases where larger gas weights are handled, with generally, lower temperature differences, the area, length and arrangement of the pas passages must be very carefully considered in order to obtain transfer rates for an absorption comparable to direct fired practice, and so extract the maximum heat from the gases with an amount of heating surface which will make the installation of a waste heat boiler a commercially economical proposition.

It was principally for such work that the experiments on heat transfer above referred to were undertaken, as with waste gases, the radiation factor being largely negligible, it is possible, with a proper knowledge of the laws governing heat transfer, to calculate very closely the results that will be obtained with a given boiler and vice versa to design a boiler to give the maximum return for the investment.

The results of the investigations are given graphically in Fig. 4, which shows the effect of gas velocity on heat transfer rates. For ease in computation, owing to the variation in density of the gases with the temperature, the velocity is considered in terms of gas weight per unit area.

It will be seen that at low rates of gas flow, as found generally in boiler practice, the transfer rates are affected by the velocity to a much greater extent than by any rate of temperature difference, also that the effect of temperature difference increases as the rate of gas flow increases. The effect of gas velocity on heat transfer rates. For ease in computation, owing to the variation in density of the gases with the temperature, the velocity is considered in terms of gas weight per unit area.

It will be seen that at low rates of gas flow, as found generally in boiler practice, the transfer rates are affected by the velocity to a much greater extent than by any rate of temperature difference, also that the effect of temperature difference increases as the rate of gas flow increases. The effect of gas velocity on heat absorption had previously been appreciated to a certain extent, but its full importance for waste heat work, as brought out by these experiments, has led to developments in boiler design which has opened up this field to a remarkable extent.

Up to a comparatively few years ago, when boilers were installed to utilize the heat in the waste gases from furnaces, kilns, etc., it was the practice to use boilers of the same general design as for direct coal fired puposes, or even with still larger gas passages in order to interfere as little as possible with the draft at the primary furnace. This meant working on the upper part of the curve, Fig. 3, and necessitated the provision of such an excessive amount of boiler heating surface for the steam produced that the installation became a doubtful investment.

Following the better understanding the laws governing heat transfer and the possibility of economies from the utilization of a greater proportion of the heat from waste gases, this subject has been receiving particular attention during the last few years and efficient boilers are now in successful operation in connection with all kinds of kilns, furnaces and ovens with temperatures as low as 1,000 deg. F.

The high gas velocities necessary for efficiency in waste heat boilers results in greatly increased frictional resistance through the setting, the draft loss running in many cases to over 2 in. water pressure, and, of course, requiring the use of induced draft fans to handle the gases. The power required to drive the fan is, however, many times offset by the increased efficiency and capacity obtained, while, in many cases, the installation of waste heat boilers has actually resulted in an increased output from the primary furnace owing to the possibility of greater draft at the outlet by the use of a fan in place of the original chimney.

Many factors have to be taken into consideration in waste heat boiler work, peculiar to the particular nature and origin of the gas, for instance, the dust held in suspension in many forms of waste gases, especially from cement kilns, has a considerable influence on the weight of gas handled and the draft resistance, and a knowledge of the effect of such factors and the proper way of taking care of them can only be obtained by experience.

A good story is told of an Englishman who was being entertained by some Americans in New York City. At the conclusion of a story, told by one of the Americans, everybody except the Englishman burst out laughing. The story-teller was rather nettled at the Englishman's unsmiling face and remarked: "I have always heard that Englishmen are lacking in humor; perhaps our English friend will see the joke and laugh next year."

Very seriously the Englishman said: "No, I shan't laugh next year for the reason that I laughed at that joke last year, and I always make it a point never to laugh at the same one twice."

Electrical Energy Generating Stations—IV

The Third of a Series of Articles Dealing With the Design of the Power Plant. This Article Discusses the Adaptability of the Three Different Classes of Prime Movers for Different Services

By TERRELL CROFT

APPLICABILITY OF ENGINES.

(1) Non-condensing units, direct-connected or belted and used for driving.

(a) Electric generators of all classes excepting exciter sets of small capacity, unless belted from the main engine.

(b) Centrifugal pumping machinery, operating under variable head and quality conditions, and at relatively low head, say up to 100 feet, depending on the capacity.

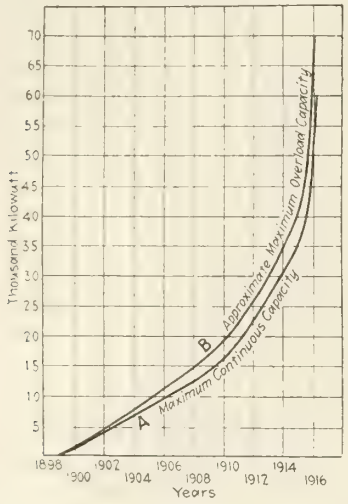

Fig. 36—Graphs showing how the capacity of steam-turbo-generator units has increased with the development of the art.

(c) Pumps and compressors for delivering water or gases in relatively small quantities and at relatively high pressures—in the case of pumps at pressures above 100 lb. per square in., and in the case of compressors at pressures from 1 lb. per square in. and above.

(d) Fans and blowers (including induced draft fans) for handling air in variable quantities and at relatively low pressures, say not over 5-in. water column.

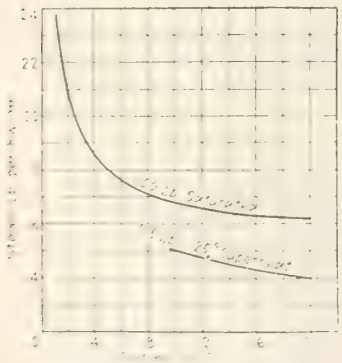

FIG. 37—STEAM CONSUMPTION OF SMALL TURBINES.

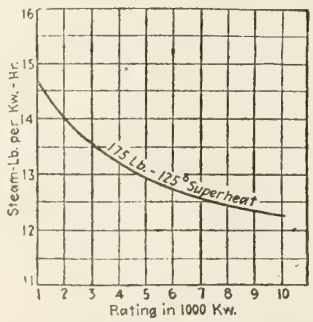

FIG. 38—STEAM CONSUMPTIONS OF STEAM TURBINES OF MODERATE CAPACITIES.

(e) Line shafts of mills, where the driven apparatus is closely grouped and the load factor is good.

(f) All apparatus requiring reversal in direction of rotation, as in hoisting engines and engines for traction purposes.

(2) Condensing units direct-connected or belted, for all the above purposes, particularly where the condensing water supply is limited, and where the water must be re-cooled and re-circulated.

*The Steam Consumption of Small and Medium-Capacity Turbines** is indicated by the graphs of Figs. 37 and 38.

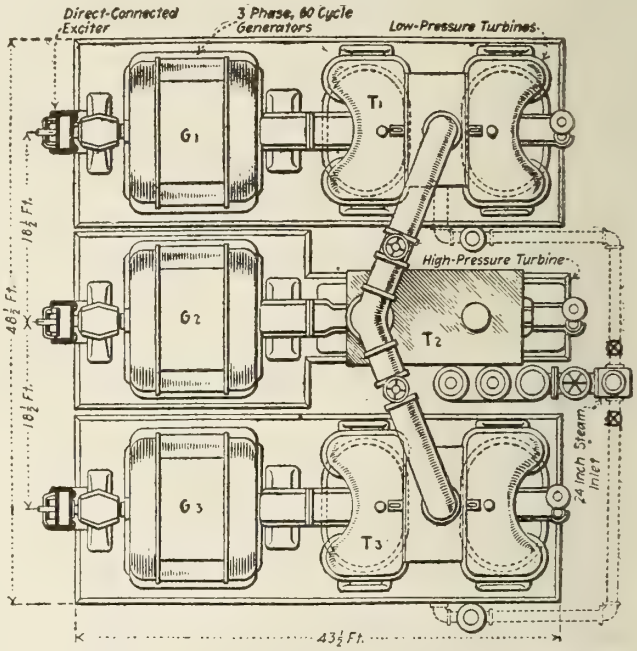

FIG. 40—THREE CYLINDER TWO-STAGE TURBO GENERATOR UNIT OF 60,000 KW. CAPACITY.

The graph of Fig. 37 indicates the economics which may be effected through the use of a high steam pressure and superheat. Fig. 39 indicates the approximate cost of small and moderate capacity turbo-generator units.

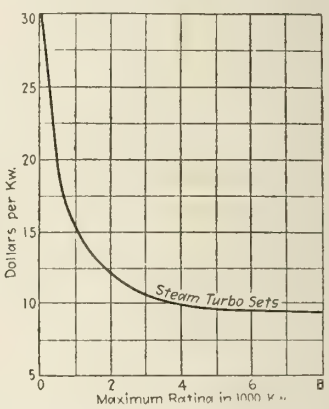

Fig. 39—Approximate relative costs of turbo generator units. (Cost of labor and materials are now fluctuating so widely that it is not feasible to give actual costs.)

The Cross-Compound Principle as Used in Large Turbines is shown in Fig. 40, which illustrates the 60,000-kw. three-cylinder, two-stage unit purchased by the Interborough Rapid Transit Company, of New York. Tests on this unit indicate at the point of maximum efficiency a water rate of 11.25 lb. per kwh.

arrangement of the power plant of the Remington Arms and Ammunition Company, at Bridgeport, Conn. The generating unit shown has a capacity of 2,000 kw.

Boilers for Steam Generating Stations are, in moderate and large capacity plants, always of the water-tube type, inasmuch as this is the only type which will permit of the use of high steam pressures and the ready utilization of economizers and superheaters. While in some quarters

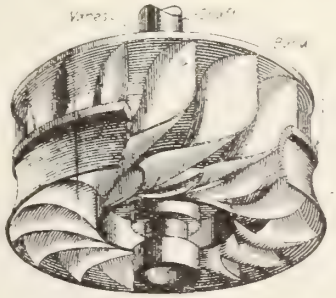

FIG. 56—RUNNER OF A MIXED FLOW TURBINE

the feeling exists that 1,200 horsepower is as great a capacity as is desirable for one unit, boilers rated at 2,400 horsepower each have been used in certain installations. In medium-capacity plants, the capacity of each boiler unit is about 500 horsepower. Fire-tube, that is, return-tubular, boilers, are now used only in the small non-condensing plants.

a fire aisle. The illustrations show some of the different methods of boiler arrangement that have been utilized in practice

INTERNAL COMBUSTION ENGINE STATIONS.

IN INTERNAL-Combustion-Engine Stations, a prime mover may be either a gas engine, usually supplied with producer-gas or an oil engine. The producer-gas installations are suitable only for plants of medium or relatively-large capacities and, as above suggested, a

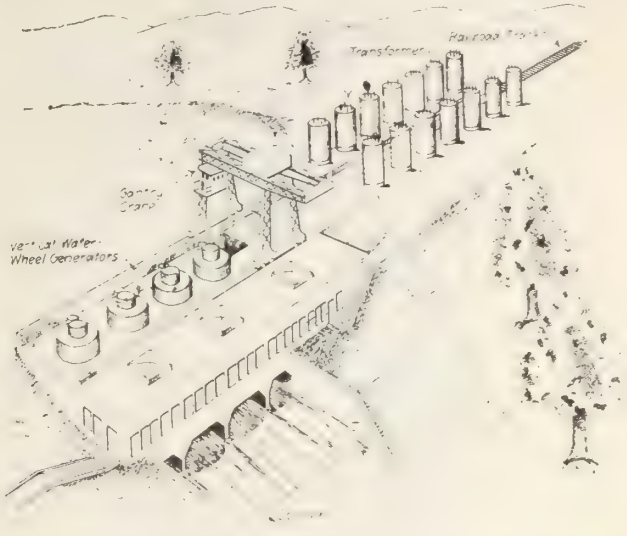

FIG. 70—SHOWING PROPOSED ARRANGEMENT OF THE PROPOSED OUTDOOR HYDRO-ELECTRIC STATION.

steam turbine is more economical in most installations of this character. The oil engines have been used to a considerable extent in medium-capacity plants in locations where the cost of oil is low. For very small plants which give service for a portion of the time, such as lighting plants operating in small towns only during the night, small oil engines are more economical than prime movers of any other type. Large gas engines have been used

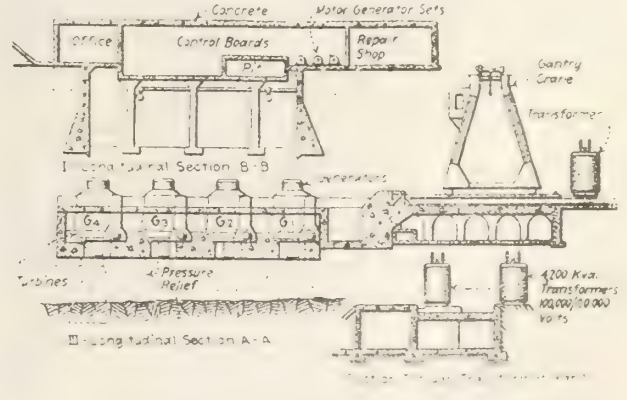

FIG. 71—SHOWING VARIOUS SECTIONS TAKEN THROUGH THE OUTDOOR HYDRO-ELECTRIC STATION.

with great success in steel plants where by-product gas for every operation is obtained from the blast furnaces. Such installations are, however, of a specific character and can hardly be classed as central station plants. Gas Engines have been built for use in these plants in capacities of 4,000 to 6,000 horsepower output each.

The Efficiency of an Internal Combustion Engine Increases With the Load (Fig. 47) so that the most efficient load for any internal combustion engine is the greatest load which that engine will carry. It follows that internal-combustion engines should be, and are, rated on the maximum basis. That is, they are not rated with overload capacities.

Oil Engines for Small Town Electric Lighting Plants are usually of the hot-bulb (Fig. 48) type. These can be operated on crude oil or kerosene. It has been found most economical in certain small plants to use kerosene rather than crude oil because, in order to obtain a low rate per

gallon, the crude oil must be purchased in tank-car quantities. In one of these small plants a considerable period elapses before a tank of oil can be consumed. Hence the charges on a container required to store the tank of oil, more than offset the difference in cost between the crude

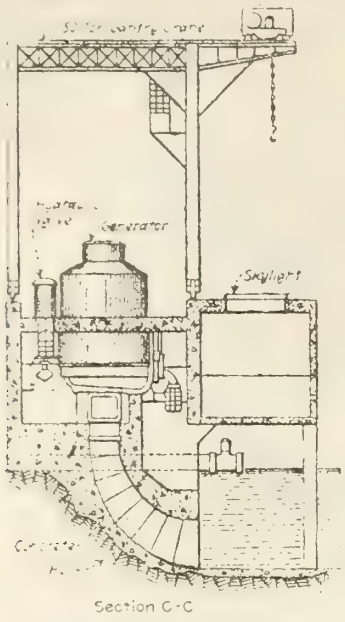

FIG. 73—SECTION C.C. THROUGH THE GENERATOR PLATFORM.

oil and the kerosene. Kerosene can be obtained in practically any locality in relatively-small drums.

The Lay-Out of a Small Oil Engine Plant is shown in Fig. 49. A plant of this type might serve its consumers through a distribution system similar to that diagrammed in Fig 5. The prime mover consists of a 30-horsepower, 400-r.p.m. Remington oil engine, which drives a 15-kva. belted generator. An economical construction for a building to house an equipment of this character is shown in Figs. 50 and 51.

HYDRO-ELECTRIC STATIONS.

Hydro-Electric Stations May be Divided Into Three General Classes: (a) *Low-Head Stations*, 4 to 25 feet; (b) *Medium-Head Stations*, 25 to 300 feet; and (c) *High-Head Stations*, 300 feet to 3,000 feet and up. Fig. 52 gives a graphic definition of the meaning of the word "head."

Water-Wheels May be Divided Into Three General Classes: (a) *Gravity;* (b) *Reaction;* and (c) *Impulse.*

A Gravity Wheel (Figs. 53 and 54) is one which develops its power by virtue of the weight of the water falling through a distance equal to the head. The falling water carries the buckets which catch it with it as it goes down and thus develops power.

A Reaction Wheel (Figs. 55 and 56), is one which develops its power by virtue of the reactive pressure of the streams of water upon the movable buckets from which the streams are forced by the head of the water above.

An Impulse Wheel (Fig. 57), is one which develops its power by virtue of the force exerted by a stream of water which issues from a nozzle or guide and impinges on buckets on the rotating wheel. The nozzles or guides are stationary and the wheel rotates.

NOTE. That the gravity wheel develops its power solely by virtue of the weight of the falling water, and that the reaction and impulse wheels develop their power by virtue of the potential energy due to the weight of the water which is first changed into kinetic energy.

The Efficiency of a Water Wheel decreases both above and below the point of maximum efficiency, as shown in Fig. 58. This fact must be recognized in selecting the generator which is to be driven by a water-wheel unit.

The Applications for the Water-Wheels of the Three Different Types may, in a general way, be given thus: Gravity wheels such as that illustrated in Fig. 53, are desirable only for very-low heads, and for the development of relatively-small power outputs. They have been used successfully in certain very-small central station installations, in which the generator is belted to the wheel shaft. The reaction wheels are best adapted to relatively-low heads and large quantities of water. In recent years, reaction wheels have been used for all ranges of head from 600 to 700 feet, for large units. The impulse wheel is best adapted to high heads and small quantities of water. Thus, for heads greater than 200 feet, and of small flow of water, the impulse wheel is the most effective prime mover. The efficiencies of water wheels may, for large units, be as great as 80 to 90 per cent.

The Names of the Elements of a Hydro-Electric Installation are given graphically in Fig. 59.

The General Tendency in Hydro-Electric Station Design has been outlined by W. R. THOMPSON*. There is a tendency to do away with the clear spillway, hence, reservoir-level-controlling devices, either in the form of Tainter gates or automatic-flash boards, are used. Frequently, the nearly-constant reservoir level has many advantages such as minimizing the investment in reserve land to that land which is ordinarily submerged. It insures the advantage of a more uniform head on the plant and facilitates the handling of the ice which forms on the reservoir.

*W. R. THOMPSON, *"Tendency in Central Station Design,"* *Electrical Review*, March 3, 1917.

This latter consideration is important on logging streams where logs are embedded in the ice. The modern tendency, specially for low-head plants, is toward units consisting of the vertical, single-runner, large-capacity turbine (Fig. 60), with a direct-connected generator. Where a set of this type is used, economy in space results, and maximum reliability is insured, due to the accessibility of the wearing parts for inspection, adjustment, lubrication and repairs. The enclosed-and-heated forebay is now being used in Northern climates to prevent the interference by ice with operation. The continued use of a submerged forebay is justified because it eliminates practically all floating materials from the rack. Where conditions affecting the choice and size of units permit, there is a tendency to reduce the number of units in the plant to say three or four, rather than to have a large number of relatively-small units.

The Typical Arrangement of a Low-Head Hydro-Electric Generating Equipment is shown in Fig. 60. This provides about as simple and effective arrangement as can be designed. The turbine and the generator are both of the vertical type and are direct connected so that there is no unnecessary friction lost in gearing or belting. The weight of the water-wheel, the pressure of the downward water thrust and the weight of the revolving part of the alternator, are carried by a thrust bearing located in the top o fthe generator. The guide bearings are self-aligning, so that cramping cannot occur. No step bearing is necessary or provided in the water-wheel.

A Low-Head Hydro-Electric Plant with a Horizontal Turbine is shown in Fig 61. With this arrangement, the generator is direct connected to the turbine shaft and the water is impounded against one of the station walls. A modern low-head relatively-large capacity hydro-electric station is illustrated in Fig. 62. In this plant ten turbines, each developing 10,800 horsepower on a 30-foot head and operating at 53 r.p.m., are installed. The generators are 6,600 volt, three-phase, 60-cycle machines, and are rated 10,000 kva.

A Typical High-Head Hydro- Electric Station is shown in Fig. 63. The impulse wheel is of the Pelton type. The governing of impulse wheels is effected by deflecting the stream away from the buckets or by throttling it. Because of the high heads under which the impulse wheels usually operate, it is dangerous to attempt to govern by throttling alone, hence a system of governing which combines throttling and stream deflection, has been adopted.

The Largest Hydraulic Single-Runner Turbine Ever Built is of 31,000-horsepower capacity (Fig. 64), and is to be installed at the aluminum plant on the Yadkin River in North Carolina. The head is 188 feet. The speed under an effective head of 188 feet, is 150 r.p.m. An efficiency exceeding 91 per cent., at full load is expected. The generators are 13,200-volt machines, rated at 18,000 kva. The turbines were built and installed by the Allis-Chalmers Company, and the generators and exciters by the General Electric. As shown in Fig. 65, the plant contains three of these 31,000-horsepower units. No transformers are required in the station, inasmuch as the energy is generated at 13,200 volts, which is also the transmission voltage. Fig. 66 gives an idea of the complete development.

The Keokuk, Iowa, Hydro-Electric Station is shown in Figs. 67, 68, and 69. The ultimate capacity of the station is 300,000-horsepower. Energy is transmitted over a distance of approximately 200 miles in certain directions of St. Louis and other cities in Missouri and Iowa. The initial installation of turbines comprises fifteen units, each having a normal rating of 10,000-horsepower, based on a head of 32 feet. The generators have a maximum continuous rating of 9,000 kva. at 11,000 volts, and operating at 80 per cent. power-factor. The normal speed is 55.7 r.p.m. This is a 25-cycle plant. For energy transmission to St. Louis, the voltage is stepped up to 110,000. For shorter distances a voltage of 66,000 is used.

Outdoor Hydro-Electric Plants* have been proposed. Figs. 70, 71, 72, and 73, show the general construction and arrangement. It is anticipated that material economics will be realized through the omission of the building (which ordinarily houses the generating equipment) in a plant of this character. Outdoor switching and transforming stations have been in successful operation for a number of years, so there appears to be no reason why an outdoor hydro-electric plant should not be successful. The plant illustrated was a tentative design proposed by R. J. McClellan, Chief Engineer of the Electric Bond and Share Company. Climatic conditions and violent winds were the determining causes for eliminating the powerhouse superstructure. The estimated cost of this development was $70 per kw. All of the generators and transformers are located outdoors. The control boards and exciters are installed in a structure over the tail-race, where a repair shop also was located.

*Electrical Review, Sept. 25, 1915, page 689.

MONEY LOST UP THE CHIMNEY

IN THE February 20th issue of POWER HOUSE there was an interesting article referring to carbon dioxide recorders and giving figures on the heat losses due to certain high and low percentages of CO_2 in the flue gas from boiler furnaces. The heat lost up the chimney represents by far the largest item of wasted fuel in the average boiler house. There is a very definite relation between the percentage of CO_2 in the flue gas and the value of the fuel that is wasted in the form of heat discharged up the chimney. This relation is shown on the accompanying chart which has been developed by the Uehling Instrument Company, 200 Empire Building, New York, to enable the engineer to determine exactly how much of his fuel, in dollars and cents, is being wasted due to low CO_2.

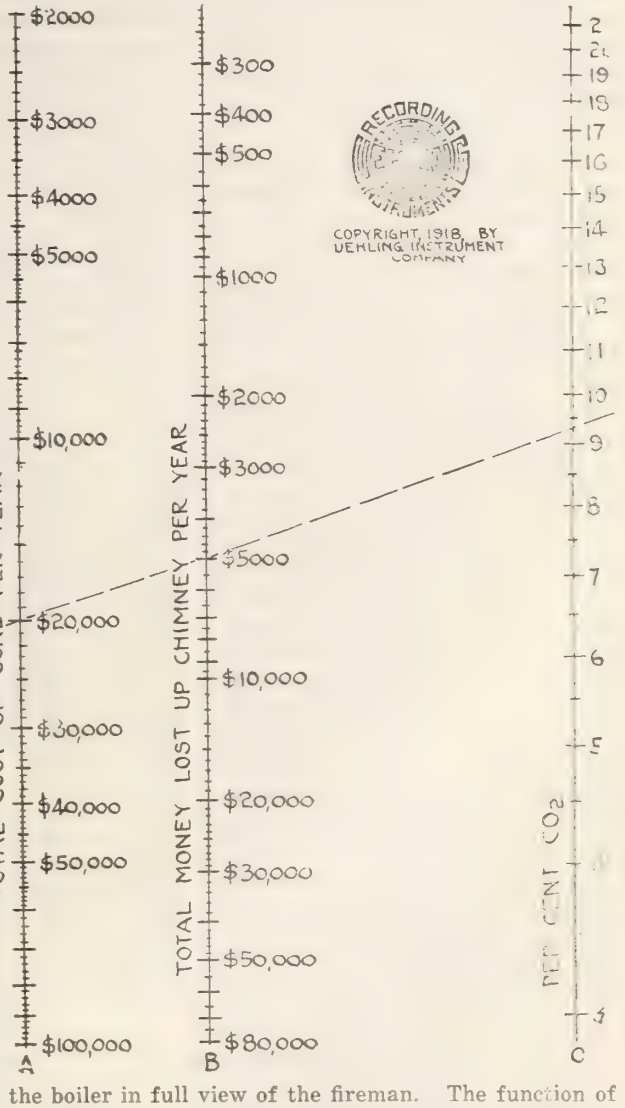
Simply connect the percentage of CO_2 (shown in Column C) with the money now being spent per year for coal (shown in Column A) and the intersection of the connecting line with Column B immediately gives the dollars rolling out of the chimney in the form of heated gases.

Example: If $20,000 is spent per year for coal burned in a furnace whose average CO_2 registers 9.3 per cent., what is the approximate money lost up the chimney per year?

Solution: Connect the $20,000 (Column A) with the 9.3 per cent. (Column C), as indicated by the dotted line drawn across this chart, and the intersection with Column B shows the approximate yearly loss to be $5,000.

The object of this chart is to show that a high percentage of CO_2 is most desirable. To be sure, even where the CO_2 is as high as 21 per cent., the theoretical maximum, there is a loss because in the average power plant the flue gases heating the boiler have a temperature as high as 500 or 600° F. Loss, therefore, is inevitable unless some sort of system is installed for either heating the feed water by means of this waste heat or preheating air and leading it under the grate.

It is significant that many of the large power plants of to-day have adopted CO_2 instruments that record automatically and continually. The reason for this is to keep constant tab on the efficiency of combustion. The recorder may be placed at any convenient distance from the boiler in the office of the chief engineer, owner, manager or superintendent, while an auxiliary CO_2 indicator is placed



on the boiler in full view of the fireman. The function of the indicator is to keep the fireman constantly informed as to the efficiency of his own work. This feature is most commendable.

Coal cannot be saved by a CO_2 machine alone. If no attention is paid to the indicator or recorder, the installation of such apparatus borders on foolishness. The records should be carefully watched and studied and adjustments should constantly be made in firing methods until the best percentage of CO_2 is obtained. After the best mark is reached, fluctuations of the CO_2 line below that mark to any great extent should not be allowed.

This chart is based on a flue gas temperature of 600° F. and an outside air temperature of 60° F. Where the flue gas temperature is higher, or the outside air temperature lower, the money loss is proportionately decreased. Further, in the construction of this chart, it has been assumed that the coal has a calorific value of 14,500 B.t.u. per pound of combustible.

The Erection of Engines and Boilers

This Article Deals With Some of the Particular Points to Watch in the Brickwork Setting of Horizontal Boilers

By T. H. Fenner

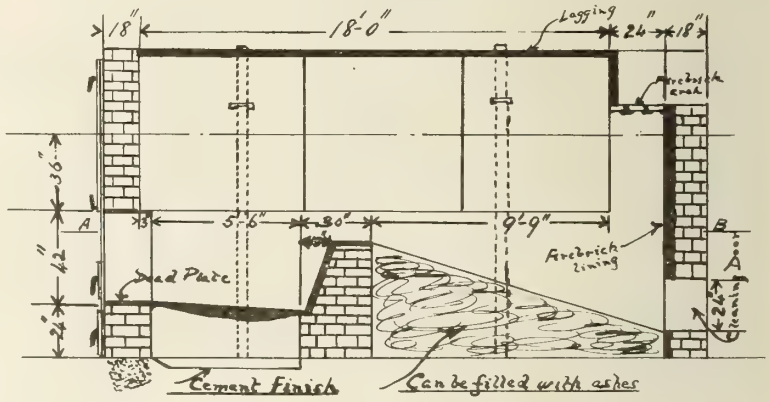
IN the previous articles on this subject we have dealt with the laying-out of foundations, excavating, making concrete forms, mixing and pouring concrete, and the handling of the boiler from the railway car to its place. Before going any further we will look into the subject of boiler settings. We need not go into the subject of water tube boiler settings here, because these boilers are almost always set up by the employees of the makers. They have a standard arrangement of setting and baffling brickwork, which is never departed from, and has been adopted as the result of much experience.

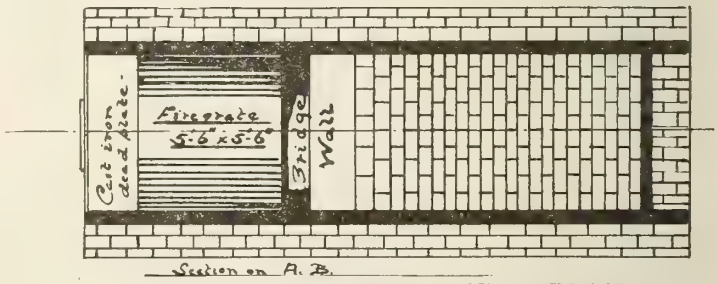
The setting of horizontal return tube boilers is also pretty well standardized, but the great trouble is that the standard is so often more honored in the breach than the observance. Horizontal boilers are so often put up in plants which are comparatively isolated, and the men on the job have the opportunity of exercising their own discretion as to the method of setting. The results are very often quite extraordinary, and the subsequent difficulty in obtaining steam is blamed on the coal, the fireman and the boiler in turn, but never on the real cause, which is the faulty setting.

In the case of the suspended boiler, the setting has no part in holding the weight of the boiler, and is therefore not subjected to any vibration, or strain from the movement of the boiler. When the boiler is supported by the walls, there is always a certain amount of racking action that tends to disintegrate the brickwork and open up sources of air leakage. The only object of a setting, when not used as a support for the boiler, is to make an enclosure which is impervious to the entry of air, excepting where openings are specially provided. An air-tight setting has not yet been made, but by close attention to the erection in the first place, and close supervision afterwards, a very fair degree of airtightness can be attained. The side, back and front walls are usually 18 inches in thickness, and where there are two boilers side by side, the thickness of the centre wall will be 24 inches and an air space of 2 inches provided in the wall above the firegrate to allow for expansion. The walls above the firebars in the furnace space, and in the combustion space, will be made with a firebrick lining. The arches and cheek plates at furnace doors, and the arch over combustion chambers, will also be composed of firebrick. It is usual nowadays to obtain specially formed blocks for these positions, which can be installed easily, without the help of a bricklayer, and usually have a long life due to the absence of joints.

The accompanying drawings show the setting of a horizontal return tube boiler, and attention is drawn to several features which require careful attention. In the first place the space above the firebars to the top of the boiler should be greater than is generally allowed in standard settings. In the accompanying sketch the height from bars to boiler shell is given as 42 inches. The usual standard boiler setting gives this height as 30 inches. Modern practice is to make this height as great as can be attained within practical limits, and some authorities claim that the furnace space should be as high as the width, or in other words, the volumetric space of the furnace should be equal to the cube of the diameter of the boiler. The reason is, of course, to prevent the cooling of the gases against the boiler shell before they are ignited, which takes place if the shell is too close to the bars. It used to be quite a common thing to find a boiler set 24 inches above the bars, and to find a very considerable deposit of non-conducting carbon deposit on the fire sheet. The bridge wall should be carried up to within 12 inches of the boiler shell at the centre of the boiler, and carried straight across. It should not be curved as, is sometimes done, to conform with the shape of the boiler.

The front of the bridge wall is lined with firebrick, as is the top, and the front should slope back as shown in the drawing. In building the bridge care should be taken to make the slope in such a way that the flame will not be thrown on to the rivets of the first circumferential seam, and in many cases the angle of the bridge will be governed by this feature. The furnace door arch may be built of brick, or as we have already mentioned, some specially made firebrick arch. In either case, care should be taken to see that the arch projects far enough under the boiler shell to protect the rivets on the head seam. This part of the boiler being comparatively cool, and a natural depositary for any scale that may be around, besides having two thicknesses of plate, requires careful protection from the heat. Otherwise, fire cracks and a leaky seam will soon develop. Another point to watch carefully is that there is no space left between the boiler shell and arch at the head, which





PLAN AND ELEVATION OF BOILER SETTING

The object of the bridge-wall is both to form a baffle for the gases going through to the combustion chamber, and at the same time, form a refractory mass which will tend to ignite any gases which might otherwise escape. From the back of the bridge-wall the floor should slope down to the cleaning door in the back wall. This floor can be faced with ordinary brick, as it will always be covered with a soot deposit which protects the face of the brick from the heat. It should be well laid to facilitate cleaning. will allow a short-circuit of the draught. It is a good plan to fill in around the edge of the shell and the arch with a plastic cement and keep this in good repair. The floor underneath the bars, in the ashpit, should be finished off smoothly with cement, and slope down slightly to the bridge wall, so that it is easy to clean out with a long shovel or rake. The dead plate should have a good bearing in the front walls. The firebrick lining should start from the level of the firebars, and carried up to the full

height of the combustion space. The brick should come in close to the boiler shell at the height of the top row of tubes. Another point to watch is the position of the arch over the combustion chamber. This should come immediately over the top row of tubes, and protect the rivet heads in the boiler head, or stay nuts as the case may be, from the hot gases. I have seen arches built so that they were 12 inches above the top row of tubes, and the rivet-heads supporting the channel iron to which the stays were secured, badly burned. There is also danger of burning the plate if the water level is not kept high, and even if the plate is not burned, the effect is bad. It can be easily understood, when it is considered that on one side of the plate there is steam or water at a temperature of about 300 degrees, while on the other there are hot gases averaging at least 1,000 degrees. With a fluctuating water level, the plate is alternately heated and cooled, setting up considerable stresses above the normal strees due to the pressure.

The junction of the combustion chamber arch and the boiler head is a difficult place to keep air-tight. Sometimes the arches are supported by a channel iron on the boiler head but this is not good practice. The arch should be supported on angle or tee irons laid in the side walls. The boiler lagging can be brought down to the top of the arch, and the joi t finished with plastic cement. However, this is one point of the setting that must be carefully watched, and kept in good repair, otherwise there will be considerable air leakage developing. Along the shell of the boiler where the fire-lining joins it is also a fruitful source of trouble from air leaking. The careful engineer will examine these daily. It is only a matter of running a lighted candle along these places, when an air leak will be clearly indicated.

Care should be taken with the fitting of the frame for the cleaning door at the back end. It should be well bedded on to the brickwork, and bolted securely in its place. It is a good idea to keep the opening inside the door filled with loose brick. This keeps the heat off the cast iron, and tends to prevent warping. In my experience as an inspector, I found leaks round the cleaning doors in 9 out of every 10 boilers I examined. Another place where there is usually a considerable leak is where the blow-down pipe comes through the setting. The hole in the wall should be bushed with a piece of pipe large enough for the blow-down pipe to come through with ample clearance and then the space around it filled in closely with asbestos. It is no use mixing the asbestos with water, in this case, for the water dries out, and the composition of course shrinks. Dry asbestos, tapped in good and tight will keep this place pretty near airtight.

Coming back to the front end of the boiler. The baffle plates on furnace doors should be kept in good repair, and the fire brick supports, or cheek blocks on which the furance arch rests, be in good condition. By taking care of these points, a long step in the prevention of warped fronts is attained, and the air leaks arising from this cause eliminated.

While the foregoing is perhaps not exactly in line with erection work, it is a subject that is closely allied with it. Further, there is so much evidence of neglect of these matters that it seems as though too much cannot be said to impress on power-plant operators the importance of these points. Looking for air leaks in a boiler setting is not as interesting as taking indicator cards, perhaps, but the right kind of attention paid to the brickwork will show more on the coal bill than a little more lead, or less compression on the indicator card.

BRIQUETTE PLANT FOR EDMONTON

Important Development to Use Tar Sand and Coal Deposits to Make Briquettes

Edmonton, Alta.—Two Chicago capitalists recently visited Edmonton to survey the field with the idea of establishing a plan to manufacture briquettes from semi-anthracite and lignite coal, which are abundant throughout the province. Part of their plan is to extract tar from the tar sands of the Athabasca River district, to be used as a binder in the briquettes.

They interviewed Premier Charles Stewart, who told them the Government would assure them aid in transporting the tar from their extraction works in the north by water route to a connection with the railway between the Peace River and Edmonton. They said they proposed to ship out from Fort McMurray, at the start, five carloads of tar daily. This output of binder would mean an immense business in briquetting. They also proposed later to supply asphalt to municipalities for road and sidewalk construction.

"There is a big future in briquetting lignite in Alberta," said Premier Stewart. "When scientifically made, lignite briquettes have a fuel value equal to anthracite. Western Canada now imports 3,000,000 tons of anthracite annually, a large part of it from the United States. With an inexhaustible supply of lignite, and with the briquetting industry established, Western Canada will be self-supporting as far as fuel is concerned and will save its present immense expenditure for imported coal."

EXPLOSION OF AN AUXILIARY STEAM TURBINE

Among the accidents reported to The Hartford Steam Boiler Inspection and Insurance Company was one of explosion of a small single stage steam turbine belonging to the Oliver Iron and Steel Company, Pittsburgh, Pa.

This little turbine stood in a sub-basement of the plant and was directly coupled to a centrifugal pump which was used for pumping water from the river. There had been some trouble with the water end of the unit due to fouling of the suction pipe, and at the time of the accident this was just thought to have been overcome and there were still a number of men standing near the little machine. The chief engineer, who was directing the starting up, stood near the water side of the machine and after it had been running for a short while he signalled to the man at the throttle to shut off the steam. At about this momtent the motor burst and the flying fragments cut an opening through the casing all the way around its circumference. One man was killed outright and four others were badly scalded by the escaping steam. One of the latter, the chief engineer, died the following day from his injuries.

The cause of this accident has been attributed to derangement of the speed governor.

STARTS NEW COMPANY

Chas. Watt, who has been associated with the Geo. F. Foss Machinery and Supply Company for the past two years, has opened an office at 212 McGill St., Montreal, and will carry on business under the name of the Watt Machinery and Equipment Company. Mr. Watt has had a wide experience in machine and engineering matters; he was born on June 15, 1877, in the town of St. Louis, Que. His early years were spent on the farm of his father, but at the age of 18 he came to Montreal and started his apprenticeship with the John McDougall Caledonia Iron Works. After five years with this firm he worked eighteen months with the Laurie Engine Company and from there he went to Dundas, working for John Bertram and Sons for two years. He then returned East to Peterborough and served with the Peter Hamilton Company for two years. In 1903 he started with the Dominion Bridge Company of Montreal, working there for ten years, the last eight as foreman. From 1913 to 1915 he was engaged in real estate activities. Early in 1915, when the demand for munitions became excessive and when executives were urgently needed, he was appointed superintendent of the shell department of the Canada Stove and Foundry Company at St. Laurent, retaining this position until 1918, when he became a salesman with the Geo. F. Foss Company, leaving there on March 15 last to open an office of his own.

Manufacturers are said to be turning their attention seriously to air cooling for the engines of small cars. "Autocar" sees in the possibilities of air cooling a chance for the British manufacturer to get ahead of foreign rivals, for in no country has more careful research work been done and more progress made in the design of air-cooled cylinders during the war.

Car Plant to Start.—The Canadian Car and Foundry Company at Fort William expect to have their plant in operation on the 3,000 cars for the Canadian Pacific Railway by June. The Company are taking on men at present to complete rush repairs on 1,500 cars for the Canadian National Railways.

W. F. Sutherland Resigns

MR. W. F. SUTHERLAND, who has been in charge of the editorial department of POWER HOUSE, is resigning his position to take up work in the industrial field. He will devote most of his time to the electrical power development side of engineering. Mr. Sutherland has agreed to ocntritueb to POWER HOUSE on electrical subjects, with which he is very well qualified to deal. The staff and readers of POWER HOUSE join in expressing good wishes for his future success.

A Personal Message

THE writer, in taking over the editorship of POWER HOUSE, does so with a deep sense of the responsibility incurred in such a step. Nevertheless the task is one which he undertakes with a great deal of pleasure, and a hope that the opportunities it opens of being of service to the stationary engineering fraternity may be fully realized. Many of the readers of POWER HOUSE are known to him through correspondence and quite a few are his personal friends. He hopes to be able eventually to include every reader in that category. The problems and difficulties that beset the path of the operating engineer are known to me through painful experience, and no one knows better the value of consultation with other men in the same profession. Every man's experience can be supplemented from that of another, and all the engineering knowledge that we have to-day is but the condensed experience and investigations of those who have gone before. The technical magazine is an open ground to which all can bring their views and experiences for the benefit of all the rest. It has sources of information that cannot be commanded by the individual, but which it makes available for every one.

There has never been a time when the technical magazine could be of greater service to its readers than the present. The work of the operating engineer calls more and more for technical knowledge, and there is no easier place for him to get it than the pages of his technical paper. It will be the earnest endeavor of the writer to maintain the high standard already set, and improve on it where possible. Criticism from our subscribers will be welcomed, and given every consideration, for the success of any journal lies with the degree of satisfaction given to the readers. On the other hand, expressions of your satisfaction are not forbidden. Having made this little editorial bow, let us all get together for the advancement of the professions.—T. H. Fenner.

The Late Olaf E. Granberg

STEAM plant owners and operators, particularly in the Province of Quebec, will learn with deep regret of the death of Mr. Olaf E. Granberg, which occurred on April 10th at his residence, Columbia Avenue, Westmount, P.Q.

Mr. Granberg's long and honorable connection with the Boiler Inspection and Insurance Co. made him widely and intimately known in steam engineering circles, and his charm of personality endeared him to all those with whom he came in contact.

He came to Canada as a boy of 7 from Norway, and settled first in the little town of Coaticook, P.Q., where he received his education. His first introduction to the engineering profession was in the Smithy of the local blacksmith, where the principal work was dressing the drills for the nearby quarries. He later entered a machine shop, and served his apprenticeship as a machinist. From there he went to the plant of the Dominion cotton mills, Coaticook, and worked up first to the position of master mechanic, and later manager.

July 1890 he joined the staff of the Boiler Inspection & Insurance Company as an inspector. As the business of the company grew he grew with it, and soon became chief inspector for Quebec district. His next appointment was that of manager of the Montreal office and later Vice-President of the company, which position he held at the time of his death. He had been in ill health for some time, and the death of his wife in January last was no doubt a contributing cause to his own demise. Mr. Granberg was 70 years of age.

His passing will be deeply felt by all his associates in the company, and by the numerous business and personal friends he had formed during his long and useful career.

Do Mergers Increase Prices?

THE matter of the big steel-shipping merger, now completed, came up in the House at Ottawa this week, and the question was put whether the Government intended to stop it.

"This new merger," said one member, "is capitalized at nearly a billion, and is almost consummated. The question is whether the Government should not take steps to stop this huge merger, which will most likely result in an increase in rates."

It would be interesting for this member of the Dominion House, seeing that the Canadian merger is primarily a steel concern, to look over the trend of prices of steel on this continent.

He might be surprised to learn that Canadians—and we depend largely on United States for steel—have bought at a much lower rate from the United States Steel Corporation than from any of the independents and smaller mills.

The United States Steel Corporation adhered to the regulated schedule of March 21, 1919, and is still very close to it.

The independents, on the other hand, are selling steel at a stiff advance over the March 21 schedule.

The U.S. Steel Corporation has been, and is yet, the one agency that has stood in the path of a runaway steel market.

There seems to be an opinion that the word "merger" implies a gouging of the people. In the steel trade the evidence does not bear this out.

There is right now a concrete example in the steel trade of this continent. In fact it is so marked as to lead to the belief that the Steel Corporation is too low or the independents and premium mills too high—and in this connection it is well to remember that the Corporation is neither passing up dividends nor going into liquidation.

Hitching His Apple-cart to a Star

PERPETUAL motion and like vagaries of the human mind have many variations, and to list them would require an ambitious volume, which, while undoubtedly large, would prove to be most fascinating reading. The modern phenomenal advance in matters electrical has, as may well be imagined, given considerable impetus to schemes intended to hitch terrestrial magnetism to some novel scheme for the furtherance of man's well-being. "Refrigerating World," of New York, has unearthed the latest of these and describes it in the following words:

"And now comes forward still another scheme to disturb the peaceful dreams of the ice and refrigeration industry. Dr. Harry Barringer Cox, whose work in the invention of the dry battery, the ground wireless and many other contrivances, has made him known throughout scientific circles, announces that he has succeeded in harnessing the magnetism of Mother Earth in such a way as to keep fruits and vegetables fresh indefinitely without the aid of the ice-man, canning, chemicals or the drying process. Dr. Cox gave this startling information to the world in New York this month upon his arrival from California with a mysterious looking suitcase which, he said, contained all the necessary paraphernalia to rob death of all of its sting for an apple, or an orange, after it is plucked from its parent stem. Ignoring Dr. Einstein and his pet theories entirely, Dr. Cox insists that he has harnessed magnetism to his purposes, and at his hotel in New York he displayed to the newspaper men alleged indorsement of his apparatus from the United States Department of Agriculture, California Fruit Growers' Association and others. At the same time the inventor claims that his process would prevent waste amounting to $1,000,000,000 a year. The only consolation afforded the ice-man is that this enormous saving will enable him to supply plenty of ice to the poor through civic committees during the dog days when ice is scarce.

"In his demonstration before the New York reporters a box about the size of a suitcase was shown containing tin cans. A copper wire was attached to the radiator and run through the bottom of the box. This wire was attached to a 'vitalizer' at the bottom of each receptacle. The doctor explained that the wire could be attached to a gas or water pipe or any metallic substance connected ultimately with the earth. In bringing the suitcase from California he drew the magnetism from the earth by attaching the wire to the steel construction of his Pullman, thereby securing the connection through the rails. Ships make a connection through the water.

"In the aforesaid tin containers the doctor exhibited oranges that were as firm and cool as if just picked in the morning when the dew was on the vine. In fact, the fruit exhibited was slightly covered with moisture. Potatoes, carrots and other vegetables several years old were also shown in the same condition. The theory of this method of preservation is, to state it in simple language, that by establishing the proper connection with the magnetism of the earth the fruit remains in exactly the same condition as when growing on the trees. In short, the magnetic connection is the tree itself.

" 'Vegetation,' he said, 'is due to the action of radioactive rays of the sun, which are produced in the earth and which through this new method may be transmitted by metal connection to any vessel and the products contained therein. The process going on in the vessel is exactly the same as that which goes on in the earth, and as long as it is undisturbed the preservation is of indefinite duration.'

"The doctor failed to explain, however, why the fruit and other products do not continue to grow as they do under natural conditions and eventually decay."

New York Gets After The Gouger

SEVERAL meetings have been held at different points to protest against the prices of potatoes, sugar, etc.

These meetings afford a good chance for people to state their case. Misery likes company, hence the sessions are well attended.

Farmers sold lots of potatoes in the fall for $2 and $2.50 per bag. That price represented the finished article. All the necessary labor had been expended. The difference between that price and the present $7 and $8 per bag represents the amount of gouging that has been going on since.

It is also a monument to the inability of the Government officials to put a crimp in the profiteers.

This week three dealers in New York City were arrested for profiteering. That is exactly what they call it.

They don't throw up a smoke screen and call it the high price made necessary by excessive production costs.

The first two arrested in New York were charged with selling 5,000 pounds of sugar at 25½ cents a pound, which they were alleged to have secured for 14 cents. The third sold at 22 cents and made 8 cents a pound. Bail is set at $1,000 each.

The jail is a mighty good place for the gouger and the financial glutton. Too bad that lenient officials admit that bail applies in all such cases.

Chance To Start Right

THE Secretary of the Navy at Washington is offering a lot of vessels for sale at bargain prices. That's what he means, although the official document puts it that they are "appraised low for immediate sale."

There seems to be a very good opportunity for some of the malcontents to start a brand new war. They could start out with buying a cruiser. There's a nice one offered for $225,000. No guns go with it, but these can easily be secured.

Then there are patrol boats, yachts, tugs, etc., in fact, everything except first-class battleships.

If you are not satisfied with present conditions, step right up and buy a fleet.

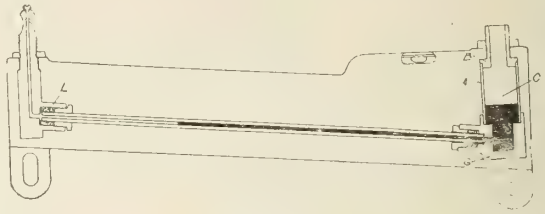
Progress in New Equipment

HAY'S DIFFERENTIAL DRAFT GAGE

The accompanying illustrations show the general arrangement and details of the Hay's Differential Draft Gage. The following description shows the various points which constitute its special features.

The oil chamber "O," is composed of a brass tube, "A," of uniform diameter, sweated to the machined parts "B" and "C." See detail 1.

The glass indicating tube is fixed in the base of the old chamber by a compression nut set against cork washers. The result is an oil tight joint, the indicating tube being held firmly but not rigidly. A similar connection is made with the machined part, "L," Fig. 8, which constitutes the air vent or pressure connection.



DETAIL 1.

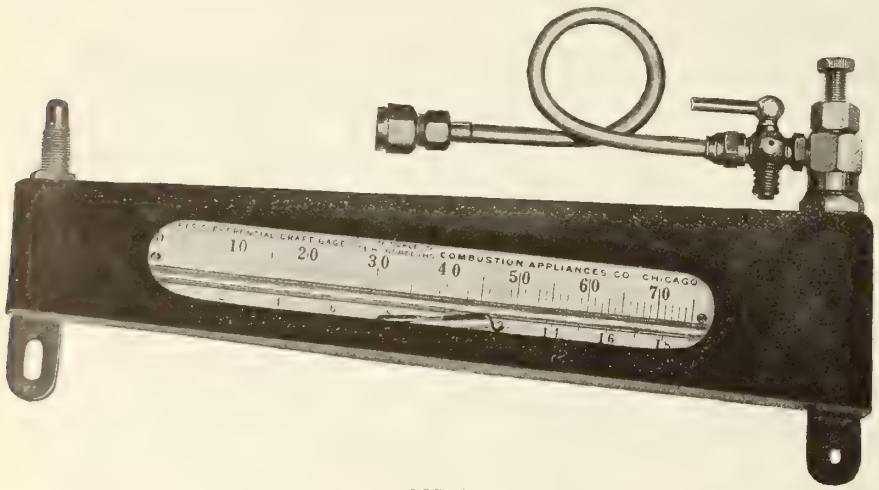


FIG. 1.

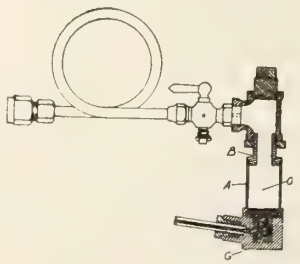
Glass tubes are never uniform bore. Furthermore it is impossible to heat a glass tube to the fusing point without affecting the walls of same. It is essential to the accuracy of a draft gage that the oil chamber be of standard and uniform bore, otherwise the indications at some point upon the scale of the gage may be inaccurate.

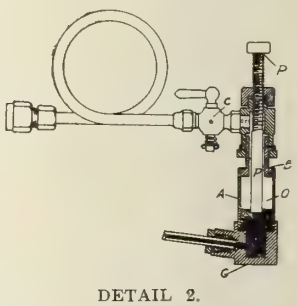
Hay's draft gages are made to stand the hard work of the boiler room. They are accurate at all points of the indicating scale. Detail 2 shows a device, patent applied for, to bring the oil quickly and accurately to the zero mark on the indicating scale. Engineers will agree with us that it is a fussy job to bring the oil to the proper point where the dropper is used. It is absolutely necessary to use a light oil as an indicating fluid. No. 300 Mineral Seal is the oil used and it will evaporate. It is therefore necessary to verify the gages occasionally for the zero indication. This is done by turning the cock "C" detail 3, and throwing the gage on air. The divide shown in detail 2 obviates the trouble with the dropper.

When the gage is first filled oil is introduced until it stands in the indicating tube at a distance of about five points from the zero mark. The plunger, "P" detail 2, is then attached and the plunger head is screwed down until the displacement causes the oil to reach zero. Thereafter when testing for zero it is necessary merely to screw the plunger down further to bring the oil quickly and positively to the zero point. When the plunger reaches the bottom of the oil chamber it is necessary to remove it and add more oil. Hay's draft gages are the only ones upon the market equipped with this device. It is an exclusive Hay's feature.



The flexible connections furnished with Hay's gages take care of all expansion and contraction that may take place between the gage and the solid iron pipe leading into the furnace. Detail 3 illustrates the flexible connection, another exclusive Hay's feature.

The furnace room is often a poorly lighted place and it is essential that the gages be clearly readable in a dim light. The scales are etched in black upon a silver plated background. The readability is further enhanced by the wide glass-covered opening of the gage front.



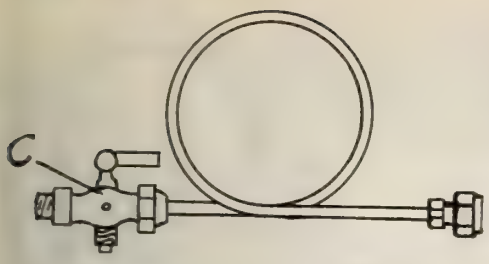
DETAIL 2.

Markers are furnished with Hay's gages arranged to ride upon the scales and may be set where desired after the gages have been erected.

THE NOKUT VALVE

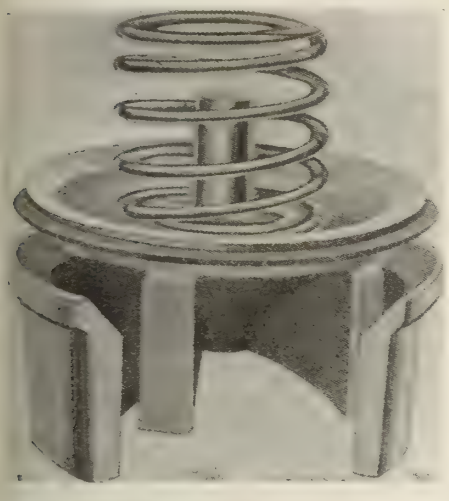
The accompanying illustrations shew two styles of valve, the NoKut standard type, and the NoKut pot type of pump valve.

These valves are claimed to be a very superior design. The valve disc is made of arpecco metal, which combines strength with light weight. A groove in the outer circumference of the valve



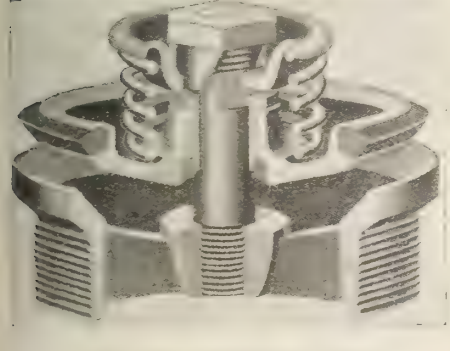
disc holds a composition ring, the function of which is to hold the disc tight against the seat when the valve closes. A similar ring is fitted on the edge of the stud hole, which prevents leakage between the valve disc and the stud.

The valve seats and discs are bevelled at the contact edges, and the water is



NO KUT POT TYPE VALVE.

not violently deflected from its course owing to the clearer passage provided the valves are not given so great a lift, and therefore work with less shock. A feature of the valve disc that will appeal to all pump users is the fitting of a brass bushing in the stud hole, which can be renewed as occasion requires. This effectually overcomes one of the



NO KUT STANDARD TYPE

most troublesome features of the ordinary pump valve operation.

It is claimed that the flexible composition sealing ring will keep the valve tight regardless of the condition of the valve seat. This has been put to an interesting test, in which the valve seat was grooved deeply with a file all round the circumference, and then subjected to a pressure of 300 lbs. for a period, without leaking. The valves are said to be very durable, with repair costs reduced to a minimum.

They are made by the Richardson Phenix Co., Milwaukee, Wisconsin, who have issued a well illustrated catalogue dealing with their product.

NEW JEFFREY CATALOGUE

The Jeffrey Manufacturing Co., Columbus, Ohio, have issued Catalogue No. 259, illustrating and describing their type "E" swing hammer shredder (ball bearing), for reducing wood chips, bark, and other fibrous materials.

Particular attention is called to the simplicity of design in the type "E" shredder, the provision made for capacity, for durability and accessibility of working parts and its easy adaptability to the handling of a variety of materials under different conditions of installation and operation. It is equipped with the highest grade radial ball bearings, which eliminate all bearing troubles and insure maximum service.

The new catalogue illustrates numerous installations and also contains engineering information, plant layouts, and other data of service to plant managers and superintendents.

The handling of coal from railway car to bunker or storage pile is an ever-present problem with many power plant executives. The latest equipment designed to meet this problem is the American Steam Conveyor Corporation, 326 West Madison Street, Chicago, Illinois.

The equipment consists of an overhead trolley, operated on either a monorail track or suspension cable. A hoist is used to lower and move a one-ton, self-dumping bucket, in which the material is carried.

One man handles the carrier in all its operations—loading, hoisting, conveying, dumping and returning the bucket. He is not obliged to leave his station at the hoist at any time. An average of thirty tons of coal can be handled an hour. Five or six cars can be emptied during the day.

The cost per ton of coal handled is extremely small—three or four cents—as contrasted with the usual eighteen or twenty cents entailed.

The equipment is completely described in a new catalogue just issued, entitled "The American Trolley Carrier." Copies will be sent to interested readers on request.

NEW PUBLICATION

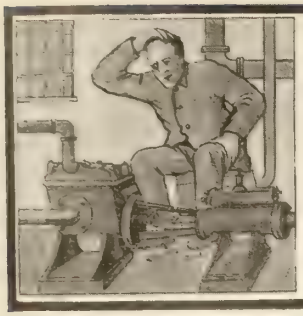
The hot-process water softener is described in a book recently issued by the H. S. B. W., Cochrane Corporation, formerly the Harrison Safety Boiler Works, of Philadelphia, Pa. The hot process softener is a modern development of the well-known lime-soda process softener, the difference being that the chemicals are added to the water only after it has been heated to 205 degrees Fahr. or higher, which results in practically instantaneous and complete chemical reactions and in more rapid settlement of the precipitate. The result is a considerable reduction in the time required for the sedimentation so that the apparatus can usually be installed within power plant buildings and without requiring special foundations or housing. The fact that the feed water heater is combined as part of the apparatus also reduces the complications and the expense of piping, etc. It is also claimed that the maximum reduction of scale and sludge-forming matter is obtained with a minimum excess of reagents and that there is no after-precipitation or troublesome deposits of scale and sludge in pumps, piping, feed water heaters and boilers, while due to the reduced solubility of the products in hot alkaline water, the minimum amount of sludge-forming solids enter the boiler and the tendency to priming and foaming is minimized. In the present publication these statements are supported by scientific data and by the results of practical operation. An improved type of a chemical feeder designed to force the water into the softener against back pressure and a chapter enumerates the impurities found in boiler feed water and describes the kinds and amounts of chemicals necessary for their removal. The book will be of value to all concerned with the operation of steam boilers.

TRADE ANNOUNCEMENT

The Harrison Safety Boiler Works (founded in 1863), which has been carried on for many years as co-partnership by Jos. S. Lovering Wharton, William S. Hallowell and John C. Jones, has been incorporated under the laws of the State of Pennsylvania, charter perpetual, as the H.S.B.W.—Cochrane Corporation with the following officers and board of directors: Jos. S. Lovering Wharton, president; John C. Jones, vice-president and general manager; William S. Hallowell, secretary and treasurer; Horace E. Sibson general sales manager; Axel B. Wallem, general works manager.

The corporation takes over, as of date January 2, 1920, the entire business of the former firm, acquiring its assets and assuming its liabilities.

The management of the business, including the engineering, manufacturing and selling organization so long identified with the Cochrane line of steam specialties, continues as before, and hereby offers its services in the solution of problems relating to the profitable utilization of exhaust steam, and the heating, metering and softening of water. The company manufacture the following lines: Cochrane feed water heaters, Cochrane steam and oil separators, Sorge-Cochrane hot process water softeners, Cochrane V-Notch meters and metering heaters, Cochrane Flow Meters, Cochrane Marine Heaters, Cochrane precision meters, Cochrane weighing meters, Cochrane multiport drainers, Cochrane multiport valves, Creasey ice breakers.



OUR QUESTION BOX

Questions are invited from readers regarding power plant operation and difficulties encountered

Question.—Please give some information on testing small boilers hydraulically, and what percentage of test pressure should be allowed for working pressure.

Answer.—In testing a small boiler, or any boiler hydrostatically, the safe working pressure should be known first, and the hydrostatic test pressure based on the working pressure. Before testing a boiler of which you do not know the conditions, the examination internal and external should be made. The boiler should be measured up, and the calculations for working pressure made from the measurements obtained.

The leading particulars would, of course, be strength of joints, thickness of plates, heads, reinforcements of openings, diameter area of head to be stayed, size and pitch of stays. These particulars can be obtained on any boiler, no matter how small.

The test pressure should be 1½ times the safe working pressure found by calculation, and should be applied gradually by a hand pump. Care should be taken to see that the boiler is filled with water, and all air expelled. This is done by leaving a cock open on the highest part of the boiler till water appears. When the pressure is obtained, stop the pump, close the feed valve, and make a careful examination for leaks or signs of distortion of the boiler. The pressure should be kept on for 15 or 20 minutes without any appreciable loss without using the pump, if everything is tight.

Do not fall into the error so prevalent that it is possible to put on a pressure of 250 lbs. hydraulically and then assume that the boiler is therefore good for 125 lbs. The hydraulic test is merely a checking up of workmanship, and a guide to hidden weakness. The only way to arrive at a safe working pressure is by a calculation involving every factor in the boiler.

Question.—How do you calculate the horse-power necessary to run a belt driven air compressor?

Answer.—The simplest way is to take an indicator card from the compressor, and calculate the horse-power from the mean pressure as you would a steam engine. This, of course, would only give the actual work done by the piston of the compressor, but would not include friction of moving parts. The mean pressure can be also found by tables approximately. In an air compressor diagram the curve of compression lies between the theoretical isothermal compression curves and the theoretical adiabatic compression curve. As the gauge pressure increases, the difference between these two curves becomes much greater. For instance, at 30 lbs. gauge pressure the theoretical mean pressure with adiabatic compression is 21,597 lbs. and with isothermal compression 16.345 lbs. per square inch. At 100 lbs. gauge pressure the adiabatic mean is 50,878 lbs. and the isothermal mean is 30.195. When the mean pressure is known, the work done by the piston is found by the same formula as that for the steam engine.

Area of piston $\times$ mean pressure $\times$ length of stroke in feet $\times$ number of strokes per minute $=$ st. lbs. per minute. This divided by 33,000 gives the horse-power. Suppose you have terminal pressure of 100 lbs. gauge, the mean pressure would be between 50.8 and 30.1, say 40 lbs. Then

$$\frac{40 \times A \times L \times N}{33{,}000} = \text{H. P.}$$

To this add 10 per cent. for loss by friction and slip of belt.

Question.—How would you figure out the size of a steam header for a battery of boilers containing eight boilers of 150 h.p. each? What size header should be installed?

Answer.—The amount of steam generated by each boiler would be at 100 per cent. rating 150 $\times$ 34.5 and by the eight boilers 150 $\times$ 34.5 $\times$ 8 $=$ 41,400 lbs. per hour. As no steam pressure is given, we will assume steam at 150 lbs. pressure, the volume of a one pound being at this pressure 2.533 cubic feet. This gives

$$\frac{41{,}400 \times 2{,}533}{60} = 1747.77 \text{ c.f. per min.}$$

Making an allowable velocity of 6,000 ft. per minute which is a fair average we get

$$\text{Area} = \frac{\text{Cubic Feet per Min.}}{\text{Velocity}} = \frac{1748}{6000} =$$

.291 sq. ft., say .3 square feet. This multiplied by 144 $=$ 43.2 square inches. Then diameter will be

$$\sqrt{\frac{43.2}{.7854}} = 7.4,$$

which is an odd size, so that 8 inches diameter should be about right.

The table for carrying capacity of steam pipes given in Kent's book gives the carrying capacity of an 8 inch. pipe at 150 lbs. per hour which is in fair agreement with the result obtained.

CANADIAN ICE MACHINE COMPANY'S NEW PLANT

The making of refrigerating equipment is a business demanding more or less specialized equipment and plant routine. This is particularly true of the pipe work involved. Ammonia coils, condensers, etc., have to be made of such strength as to stand comparatively high pressures and at times severe conditions. During the fall of 1919 the Canadian Ice Machine Company moved to their new factory near Ashbridges Bay, Toronto. This plant is now being used for the fabrication of all the piping entering into Canadian refrigeration plants installed by this company.

The main building is 100 by 245 feet long and together with the garage carpenter shop and storehouse occupy part of the two acres of land owned by the company. Large, well-lighted offices occupy a second floor at the front of the main building and are divided into business and engineering sections. This latter department includes the purchasing, progress traffic, drafting, departments, etc. Large private offices are also provided for the executives.

The factory building itself is of the usual brick and steel construction and is so laid out that all materials progress successively from one end to the other without interference. The factory operations include bending, electric welding, acetylene welding, etc., and in addition to departments for the carrying on of these various operations a coil shop, machine shop and blacksmith shop are provided. All manifolds are acetylene welded, while a Thompson electric welder is used for butt-welding ammonia coils. This eliminates all joints and results in a perfectly tight construction, stronger than the original pipe.

All coils and pipes before shipping are tested with air under water up to 300 pounds pressure and on occasion hydraulic pressure up to 600 pounds per square inch can be used.

For the heating of the shop and office a 75 horsepower boiler is installed. The shop is heated by Vento radiation and air ducts underneath the floor, while the office is steam heated. The heating and ventilation equipment was installed by W. J. McGuire, Toronto.

A siding runs directly into the shop with room inside for two standard freight cars. Room is also provided inside for eight carloads of pipe.

The Operators' Point of View

Re the Ontario Graded Certificate Act

Correspondence

THE Editor,—I am pleased to find as I read through the correspondence page of POWER HOUSE that I have a few kindred spirits who will help in the fight to rouse the stationary engineer out of the rut he has fallen into of late years. He will sink, if let alone, more deeply into the slime of ignorance if not roused up to see the danger of his position. This may sound very harsh to the ordinary layman, but when we think of the strides that science has made during the last five years, has the average engineer tried to keep pace with it? Has he not been able to see the handwriting on the wall and that the technical man has come to stay? Why has he not in all those years with his great amount of practical ability clinched the matter by becoming technical as well? As it stands now the younger man leaps over his head, and he will gradually fall back into the far and dim past. I still look forward to a great revival among engineers in the future, but until they can see themselves as others see them their status in the world will remain that of the skilled mechanic.

I can't say I agree with our friend Mr. Noble, although the idea is a good one, I am afraid it is not practicable, because if we had so many specialists round a plant, the green eyed monster would play a very prominent part. I know I am making a very grave assertion but if any of my fellow-engineers have had the misfortune to be in a plant where so many specialists were employed he will confirm my statement. We will take for instance some ordinary plant where a master mechanic, a chief engineer, and chief electrician is employed. Each one has his own particular duties and at some part of the game all these people's duties tie in with each other. Then the petty jealousies begin to show their snakelike heads and all is discord for a time. Of course, there are exceptions to all rules. The war was won with one head so must a power house be run with one brain and the man that shows the best brains wins out in the great race of life. I still adhere to my most religious principles, "Learn more, earn more." I don't wish to come under the category of our friend "Horatio," a sore head, but I would certainly like to see the day that our engineers will arrive at the pinnacle of perfection and be a respected and much revered body of men. But they never will be so long as they are content to remain in the indolent state they are at present. The war was fought for humanity's sake and that the poor downtrodden small man might partake of the gifts the Gods have given him. Metaphorically speaking this is extended to the engineer of to-day. Is he taking advantage of the fact? If my brother engineers would only think over the matter seriously, and the time has come when they must do so, and not only think but act and by doing so we shall rise from our present position of stagnation and obscurity.

Of course I shall be slated from one end of Canada to the other, but I have the strength of my convictions, on this matter, and will state an example of the point in question, but before I do so, please understand I am not speaking individually but collectively, of the whole of Canada. In this city of Montreal the C. A. S. E. hold an educational meeting once a month where one of its members gives a lecture on the different parts of engineering, mathematics, etc. Now I know for a positive fact that this same member spends many hours getting his data together for a two and one half hour's lecture, and the material for demonstration. The lecture should be of great advantage and benefit to the members, yet not more than one-half can attend. If spoken to about it they say "I believe it was a fine lecture, but I will be there next time." Oh, that monster, "Procrastination." These are the men who when the time comes to try and climb higher and the examination has to be passed, start running around to their fellow engineers crying what are the questions? How do you do it? What are the answers? And if a doctor put his sterthoscope to their breast the beat of their heart would almost break the drum of his ear.

I am glad to say my two former letters are doing a little good here in the province of Quebec. They are going to make the examinations a little more difficult. I was speaking to the chief examiner, who is a personal friend of mine on the matter and his version is that now all the old hands had passed through he wished to make a better class of men out of the new blood. At the same time he agreed with me in the stand I have taken and his remarks were "I hope you will shake them up for they sadly need it." I know it is very hard to hear the truth, for truth is like a keen edged sword it cuts very deep, but the sooner it is faced, the better for all concerned. I would like to call Mr. Long to account over the words, "I can't pass for a first-class examination without further study. Please Mr. Long don't use that word "can't" it should be an unknown quantity in the engineer's dictionary. If all our great engineers, before our time and since, had used that slogan, where would the world be today? "Can't" did not win the war, but "will" did. Mr. Long will have read my remarks in former letters on the slang word "Wop." If he is only an ashman he is at least a man for a' that.

I hope when we hear from Mr. Long again he will speak with more confidence, and say, "I have passed," and bear in mind after the honor is obtained and he holds the much coveted certificate he must still say excelsior, and keep on grinding. Remember, to stand still means to fall back later on, and when the good job comes along you will shake your head and say: "It's too big for me." The man who has spent his time burning the midnight oil wins out, for brains tell every time, and the man who has wasted his time falls back into obscurity.

HENRY WRIGHT

Mr. Editor,—This is my last letter on this subject, and your correspondents can scold me to their hearts content in the future. If Wm. H. Long, "Wop," and others will read my letter in February 20th POWER HOUSE in which the unlucky word "wop" was used, they will note that it is stated as certain I could

not pass the present examination for first-class papers. Mr. Long tells us he can do his work as correctly as myself; I never even hinted he could not do so, quite possibly he can do it a lot better than myself, and he would not have much to brag about even at that. He further states he only had a public school education. I only had a small part of such an education, being compelled to leave school at the early age of 10 years, therefore it is small wonder that some word or expression of mine should offend the feelings of some of those who have had greater advantages than myself along these lines.

It is to be regretted that the word "wop" was used. I tried to explain what was meant by the word in a later letter and believed the explanation would satisfy most of the readers, but apparently no attention has been given to that letter One correspondent gently hints that no gentleman will use slang; these are not his words but the impression given. If this is so there are very few gentlemen in this wicked world. A slang word such as I have used is often written to save many words. It has not proved what you could call a success this time so far as saving words is concerned, but it surely has been a success in bringing a lot of new names on to the correspondence section of POWER HOUSE.

The trap mentioned by Mr. Wright is none of my designing. It was described to me and I simply passed the description along. I tried to show this in the opening paragraph of the letter. My own opinion is that the apparatus could be converted into a fairly reliable low pressure trap by making a few inexpensive changes; closing the bottom of the float for one.

In Hawkins' "New Catechism of Electricity," 1903 edition, the practical engineer or mechanic with no book knowledge is referred to as a laborer. So I am not the only "goat" (more ungentlemanly slang). Any man who has taken and passed through a school course in engineering, or made a careful study of engineering text books, must possess considerable technical knowledge. Mr. Wright "bumps" me (more slang) rather hard. He referred to a mechanical engineer with not a particle of technical education. If he had any technical knowledge, even if he secured it by or through practical experiences in working out formulas, etc. (and he could not work out engineering formulas with no engineering printed study to his credit) is it possible for any engineer to have not a particle of technical knowledge?

In every letter I have written I have tried to show that I consider it among the wonders of the world, or words to this effect, for any operating engineer to be a finished technical man.

The opinion I have tried to state is that every engineer in charge should have considerable book knowledge about engineering.

Anything printed so far has failed to change this opinion. Will any of the correspondents who have been "calling me down" (slang again) come out in print under their own name stating they believe an engineer in charge can be a capable, safe, and reliable man and still possess not a particle of book or so-called technical education or knowledge. Do not "split hairs" (confound the slang), education and knowledge are the same thing when the term is applied to a trade. It may be secured to some extent by practical experience and greatly increased by studying the experiences and experiments of those writers, past and present, who have shown us how to solve many engineering problems, many of these problems being worked out by the use of mathematics.

Like many other questions, different people have different ideas as to what constitutes a technical man. At the present time I believe most folks will admit that it is not necessary for a man to have even a high school education, or to have passed a science school examination, or hold a degree from any university, to be a technical man. There are many free technical schools, notably in the city of Toronto, that turn out many engineers every year, who are passable technical men as well as practical engineers. Understand they are technical men in reference to stationary engineering, or sanitary engineering, or to any other branch of engineering to which their studies have been applied. In a minor degree any man can secure such technical education by faithful study of the school text books in his own home, securing help by mail from school teachers on any question he finds it impossible to answer without such help. In the technical school there is a power plant and different equipment which can be taken apart and the different parts, operation, etc., of each machine described and shown to the student. It is obvious that this cannot be done for the home study man, but text book illustrations are so well made that the man of ordinary intelligence has little difficulty in understanding them with the help of the printed description.

Another thing which I have repeatedly stated is my belief that it is impossible for any man to become an expert or even a fair technical man in all the different sciences connected with stationary engineering.

JAMES E. NOBLE,
Portsmouth, Ont.

Burnt Church,
Editor: April 26, 1920.

Dear Sir: We have been asked to give our opinion on graded certificate and any suggestions that we could make. Now I think that some have been too severe on that line, either for or against, but to my mind it is not a question of doubt but what every man operating an engine should have a certificate. Now there is nothing unfair about it. Why is it a man is required to hold a certificate of any kind? Is it not to insure life and property? Now I might apply for a position as master of a vessel. Could I get it without presenting my certificate? Not at all; too much life and property involved and that is the reason why an engineer should stand an examination, of course. I have known men who knew no more than how to turn on the water and start the engine. Good, trusty fellows, but there is more required than that now. I am living in New Brunswick and I just hold a certificate of service. Have had a large experience on engines of different makes. I mostly always effect my own repairs and I can stump the country as to the care and management of engines and boilers, but I know that I could not get a position in Ontario without first standing an examination. Perhaps I should fail but nevertheless I believe in it. Pass the good stuff along. J. R. M.

TRADE ANNOUNCEMENT

The George T. Ladd Company, of Pittsburgh Pennsylvania, manufacturers of the Ladd water tube boiler, have announced the opening of a Chicago district sales office in charge of Mr. W. M. McKinstry, the address being 528 McCormick Building. Mr. McKinstry was formerly Chicago manager of the Page Boiler Company and has had wide experience in all phases of the water tube boiler field.

During the recent cold period the barometer went unusually high (30.85 in. or 30.9 in.,) and operating companies which had an eye to turbine economy increased the vacuums on their condensers as much as possible to keep up with the rise in the barometer. At the United Electric Light & Power Co.'s 201st St. Station, New York, the unusually high vacuum of 20.35 in. was obtained on its 25,900-kva. turbo-generator. The turbine is equipped with a 40,000-sq. ft. surface condenser and a Le Blanc air pump.

Put a Farnsworth System to Work in Your Steam Plant

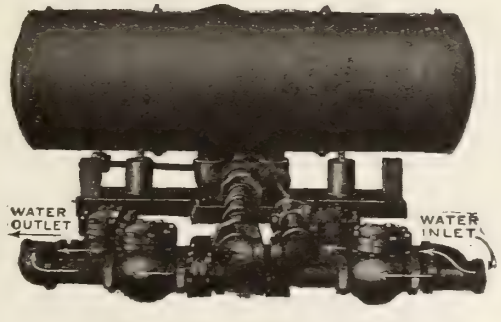
Farnsworth-equipped plants produce more steam with less fuel and less expense than other plants. Thousands of dollars are being saved by the Farnsworth System, not alone in Canada and United States, but in all countries of the world, wherever steam is used for heating or manufacturing process work—its value is thoroughly proven!

When the amount of expense saved by Farnsworth equipment is taken into consideration the question of installation costs is eliminated. It quickly pays for itself. It is a safe and profitable investment. Experience proves that in the majority of cases only three to six months' operation is required to return first costs.

These are facts. Plant owners have nothing to lose and everything to gain by investigating the Farnsworth System and the engineering staff of The Canadian Farnsworth Co. will be glad to advise and co-operate with them in solving steam line drainage and boiler feeding.

The Farnsworth Automatic Duplex Boiler Feeder

The "Farnsworth" should not be confused with ordinary steam traps. It is a machine built for Boiler Feeding. Note the cushioned dashpots, a feature which provides against shocks and ensures smooth operation.



The Sign of Coal Saving

No leaky steam valves with the Farnsworth in your plant; no constant waste of steam to the outside air; no springs to loose their tension; no levers to jump out of place; no weights to cause poundings, and no trunnions to bind and stick, or leak water and steam.

The Duplex feature of construction ensures a continuous flow of feed water to the boiler. Then, the machine being always equalized with the boiler provides against sudden shock or jar in the feed lines. There is no hold-up on the return lines as is the case with ordinary return traps, as the feeder is constantly receiving the water.

Our expert steam and condensation engineers are at your service. Have them investigate and make reports.

NEW PUBLICATION

Centrifugal pumps of the single-stage and multi-stage types for various services are described in a handsomely illustrated catalogue just issued by the De Laval Steam Turbine Co., Trenton, N.J. This company makes a practice of guaranteeing each pump fully as to head, delivery and efficiency, as well as to workmanship and materials, and each pump is tested before shipment. Manufacture is on an interchangeable basis, permitting of the supplying of finished repair parts made to accurate dimensions. The present publication describes these and other details, and also explains fully the use of pump characteristic curves in adapting pumps to various services, the drives, the information required by the manufacturer in order to design a pump to suit given conditions, etc. Formulae and tables are given for calculating horsepowers, efficiencies, the readings of Venturi meters, friction in pipe lines, etc.

Mr. Irving H. Jones, who is well known in machine tool circles in the Chicago field, has become associated with the machinery department of Joseph T. Ryerson & Son, and will specialize in sales engineering work on the Ryerson line of machine tool equipment.

Mr. G. J. Armstrong, director of the McKinnon Columbus Chain, Ltd., and McKinnon Industries, Ltd., of St. Catharines, Ont., Canada, who has been visiting Australia, returned to Canada during the past month. Edwin Wood Prop., Ltd., represent these manufacturers in Australia.

U. S. Firms in Canada.—An interesting comparison of the number of outside manufacturing firms having branch factories in Canada has been compiled by the Canadian Trade Commission. This shows that while there are scarcely half a dozen British manufacturers with branch factories here, there are some 530 American manufacturers, whose products range from farm machinery and tractors to packing house products.

Short of Material. — Speaking of shortage of material, a Hamilton despatch says: The high rate of exchange is seriously affecting local industries which have to buy materials from the neighboring republic to any large extent. All importations have to be reduced to a minimum. W. B. Champ, managing director of Hamilton Bridge Works, said that their plant might have to close down owing to inability to secure materials.

FOR SALE

Enclosed liquid fuel combustion apparatus capable of generating intense heat in pipes and confined passages for heating parts of internal combustion engines and for other uses; spark ignited; blower operated. Patented April 3, 1917. Can be inspected at and for sale by H. W. Petrie Limited, Toronto.

FOR SALE

One 300 H.P. Leonard Automatic Engine; one Closed Feed Heater; one 8 H.P. 220 v. D.C. Motor; one 15 H.P. 220 v. D.C. Crane Type Motor.

H. N. BROWN, New Glasgow, Nova Scotia.

FOR SALE

Perfected rotary engine valve, simple design, free from defects common in rotary valves. Patented Feb. 20, 1917. Can be inspected at and purchased from H. W. Petrie Limited, Toronto.

NON-CORROSIVE CYLINDER OIL MANUFACTURED ONLY BY E. H. KELLOGG & CO. NOS. 242 244 SOUTH ST. NEW YORK, U.S.A.

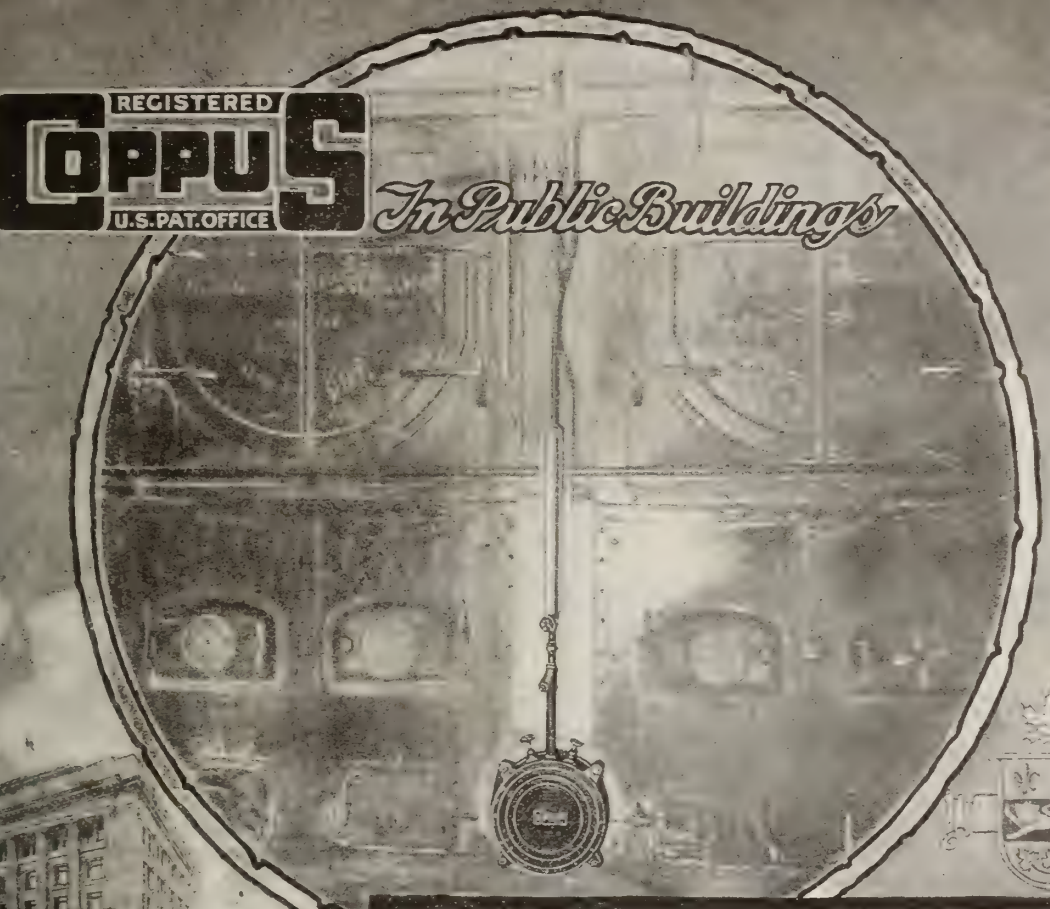
FRICTION LOSS

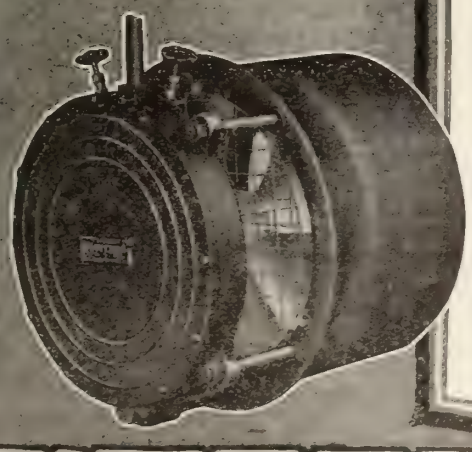
An overload is often a necessity. But it is hard on an engine. To successfully carry an overload so that there will be no after effects on the engine a very careful selection of your oil should be made. An oil that is not free from impurities will cause a greater wearing on the bearings, a great friction loss will occur. You will need to fire the boiler more often because the engine will be harder to run. In this manner you lose out. You work harder, have larger operating costs, and less power all because of your oil. Do as a great many Canadian engineers have done—give Kellogg's "Non-Corrosive Cylinder Oil" a trial. Absolutely pure. Write us regarding it.

E. H. KELLOGG & CO.,
New York, U.S.A.

REGISTERED COPPUS U.S.PAT.OFFICE

In Public Buildings





Municipal engineers **demand** efficiency—and **insist** on economy of operation. Power plant equipment, to secure the approval of public engineers, must measure up to the **highest** standards.

This 22" COPPUS Turbo Blower in the City Hall at Montreal, Canada, has been burning bird's-eye with economy, and holding steady steam pressure without difficulty for many months. Here, as in thousands of plants the world over, COPPUS Blowers burn cheap coal, save time, labor and money, and greatly increase plant efficiency.

That COPPUS Blowers are recognized as leaders in their line is evidenced in the fact that three-fourths of all the blowers made in America bear our trade-mark. Ask our engineers to show you how "COPPUS Equipment can save you money." Write for Blower Catalog.

"COPPUS" Equipment can "Save You Money"

When Buying Thermometers

There's Just Three Things to Remember—

First, you must have accuracy and sensitiveness—

Second, durability is absolutely essential—

Third, the thermometer must be suitably constructed for the intended application.

Accuracy, sensitiveness and durability are absolutely guaranteed in

"Crescent" Thermometers

And with nearly seventy years of experience to our credit, we are qualified to properly interpret your needs.
Our Catalog P.H. 200 illustrates and describes "Crescent" Thermometers for every application. Also test thermometers, glass thermometers, etc.

Get a copy of Catalog P.H. 200 to-day.

Dart Union

Never Requires Attention

Never has to be Replaced

Use Again and Again—
it's always efficient

Trade DART Mark

The Joint Stays Tight. Bronze Face and Seat prevent deterioration at the connecting point. And the Heavy Iron Parts will not stretch or pull apart under strain or heavy pressure.

Manufactured by

Dart Union Co., Limited, Toronto

When you need
fuses remember that

ECONOMY renewable FUSES

—were the first line using an inexpensive bare link for restoring a blown fuse to its original efficiency to be ***approved in all capacities***—0 to 600 amperes in both 250 and 600 volts—by the Underwriters' Laboratories.

—bear the "Und. Lab. Inspected" label. Economy "Drop Out" Renewal Links are stamped with the "Inspected" Symbol.

—long ago won public approval—evidenced by the fact that for many years millions of them have been giving dependable protection, high efficiency and working marked economies.

—cut annual operating costs 80% as compared with the use of one-time fuses.

—are used wherever efficiency and economy are chief considerations—in steel mills, manufacturing plants of all kinds, buildings, and in every branch of industry.

—are used wherever safety is the prime consideration—in powder mills, hospitals, schools and the United States Navy.

—are absolutely accurately rated, made of the best materials and by the most skilled and careful workmen obtainable.

—are sold by all leading electrical jobbers and dealers.

Insist on getting Economy Renewable Fuses.

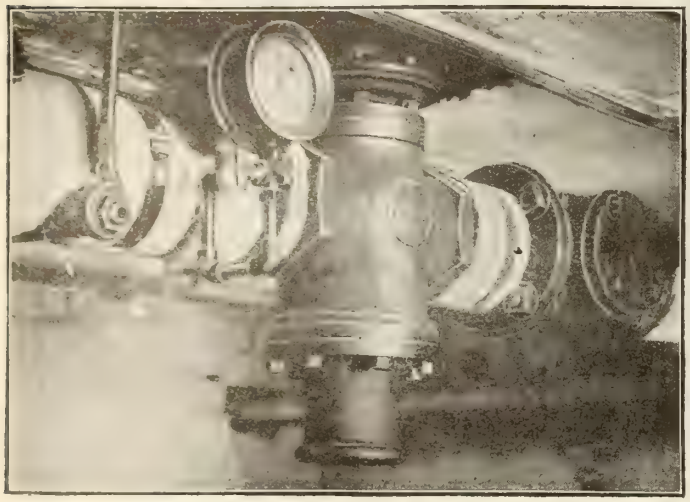
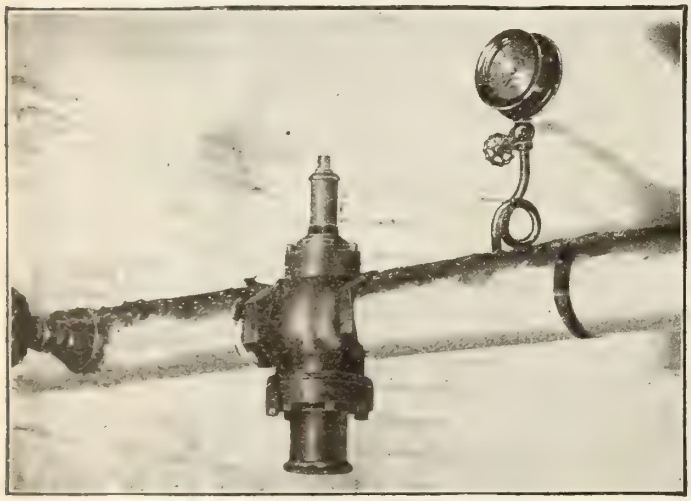
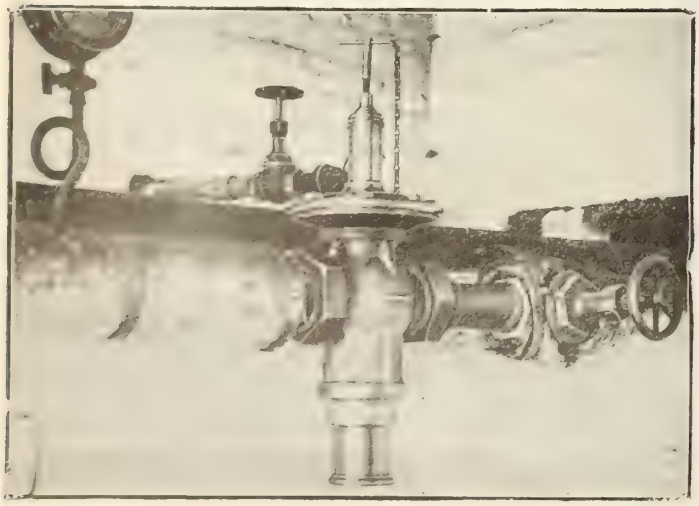
MASON'S



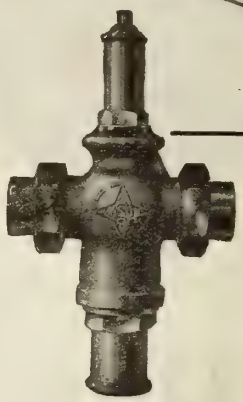
No. 1—3″ Mason Standard Reducing Valve.



No. 2—Mason 2½″ Standard Reducing Valve.



No. 3—Mason 2″ Standard Reducing Valve.



Mason Reducing Valve

What Do You Think of This Record of Service?

Twenty-four years ago (1896) two **Mason** Reducing Valves (No. 1 and No. 2 as shown in the accompanying illustrations) were installed in the heating system of the Protestant Hospital for Insane, at Verdun, Montreal. No. 3 was installed three years later.

No. 3 has never been taken out, has never been repaired and is giving the best of service to this day. Nos. 1 and 2 were given a new lease of life in September, 1919, when they were repaired with new main valves and auxiliary valves, and judging by their appearance and action they are good for many more years of satisfactory operation. Can you beat this for efficient, economical service?

The **quality** that is embodied in **Mason** Reducing Valves is seen in all **Mason** power house specialties —else they would not be associated with the Mason Regulator & Engineering Company.

The Mason Line Includes :-

"Mason" Reducing Valves (genuine); "Mason" Pump Governors; "Mason" Pressure Controllers; Bundy Steam Traps for every service; Coppus Turbine-driven Blowers; Coppus Turbine-driven Boiler Feed Pumps; Sims Hot Water Generators; Sims Storage Heaters; Sims Open Feed Water Heaters; Bundy Oil Separators; Ashton Gauges and Safety Valves; Everlasting Blow-off Valves; Babbitt Sprocket Rims; Stratton Steam Separators; Reilly Feed Water Heaters; Reilly Evaporators and Distillers; Reilly Feed Water Filters.

Remember, Mason for Service—our salesmen are practical engineers.

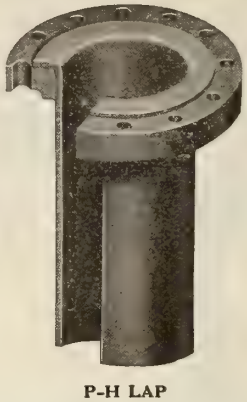
P&H FLANGED PIPE JOINTS

SCREWED



P-H LAP

P&H LAP FLANGES, for any service, have proven to be the best yet designed, and they have many advantages over other styles. The pipe is not weakened by cutting into the wall as when using screwed flanges. The gasket bears on the face of the lap and absolutely prevents leakage through the bore of the flange. The hub of the flange is bored slightly larger than the outside diameter of the pipe so that the flange will swivel readily and accommodate itself to any slight variation in the position of the bolt holes, an advantage which is obvious to the fitter and eliminates torsional strains in attaching.

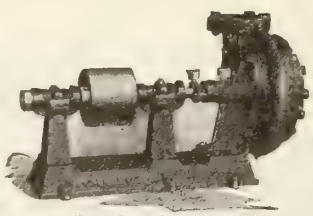
Head Office: 100 CHURCH STREET, TORONTO, ONTARIO

AMERICAN-MARSH PUMPS

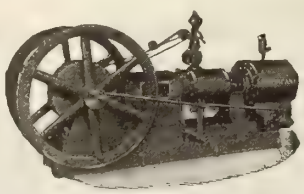
SIMPLE **RELIABLE** **EFFICIENT**

The American-Marsh steam pump is an improved form of the famous Marsh Pump which has been on the market for over thirty years, during which time over 150,000 have been manufactured and sold.

The American-Marsh Pump has no internal stuffing boxes, no tappets and no slide valves. The auxiliary valve is of the semi-rotative disc type of an improved design. The main steam valve is of the balanced piston pattern, assuring highest efficiency. The water ends have large valve areas and are fully bronze fitted, including solid bronze piston rods and bronze removable water cylinder bushings.



American-Marsh Centrifugal Pumps are made with the same high grade of material and workmanship which characterizes the construction of the steam pumps. They are made in all sizes up to 12 inch, both single and two stage for heads up to 250 feet.



The line also includes—

Power Pumps
Deep Well Engines
Air Compressors
Jet Condensers
Dry Vacuum Pumps
Boiler Feed Pumps

If You Distribute Steam for Any Purpose You Can Use "Adsco" Equipment

LET us quote on your requirements for all materials for Underground Steam Main Construction. We make a complete line of everything used in the distribution of Steam; Expansion Joints, Insulation, Variators, Valves, Manhole Curbs, Companion Flanges, Separators, Angle Joints, Steam Traps, Meters, Regulators, Heaters. We have a big stock of W. I. Pipe; Flanged Fittings, a complete line, all made from sweep-angle patterns to standard dimensions; also "Adsco" Specialties for the "Adsco" System of Atmospheric Heating.

STANDARD STEAM PIPE CASING

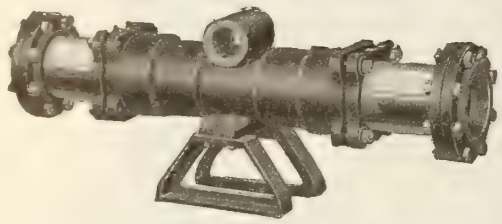
In central station heating the degree of efficiency of insulation is considered to be the percentage of heat transmitted to the consumer as compared to the total amount of heat delivered into the pipe line, and in order to secure the greatest economy in the distribution of steam through underground mains the most competent engineers have, after exceedingly thorough investigation and tests, adopted what is commercially known as "Standard" Steam Pipe Casing for insulating such mains.

GATE VALVES

A line of extra heavy gate valves for underground and interior work. Superiority of design and excellence of construction characterize these valves. See our Catalog for full details.

EXPANSION JOINTS

This company has specialized on Expansion Joints for many years. Many of these in our regular line have been developed especially for our own Central Station Heating work. We make Expansion Joints large or small, single or double, heavy or light—of every necessary type to meet every condition found in steam distribution.



Write for Complete Catalog

of Adsco equipment mentioning the particular apparatus in which you are most interested. If you are interested in heating a group of buildings or industrial homes; ask for Catalog PW on "Central Station Heating."

MORSE
CHAIN
In a Big Railroad Shop
Where Every Ounce of Power and Inch of Space Count
This Morse Chain is delivering power to a 180" boring mill from a 15 H.P. G.E. Motor running at 1200 R.P.M. The chain is exposed to all the grit and dust of the shop. It is 4" wide and connects a 17 tooth pinion with a 120 tooth wheel directly below—a distance of only 33" between centers.
No record has been kept of the age of this particular Morse Drive, but the boring mill is known to be one of the oldest in the shop and one of the first to be individually driven, so it is safe to state that this Morse Chain has been many years in service of the most exacting nature.

"Morse" is the Guarantee Always Behind the Efficiency, Durability and Service

The Most Modern Power Plant May Waste 25% of its Coal

Unless—

proper steps are taken to prevent the waste. Innumerable results have shown that 25% of the fuel burned under steam boilers is wasted by preventable losses in the boiler furnace alone.

Modern equipment alone will not eliminate these losses. Equipment is just as efficient as its operation allows.

To save that 25% you need accurate information of the furnace at all times—then the necessary knowledge to apply that information.

"When you buy HAYS APPARATUS you buy HAYS SERVICE"

The Hays Automatic CO_2 and Draft Regulator shows an accurate and continuous record of the two essential furnace conditions. Our book, "How to Build Up Furnace Efficiency" helps you interpret and apply this information.

A copy of this interesting book will prove invaluable to you. It is in no sense a catalogue — and it has gone through 14 editions.

VULCABESTON

Under All Conditions

Today, a wet steam joint under low or high pressure—tomorrow a superheat cylinder or pipe line under high pressure, or perhaps an ammonia, gas, or air compressor—no matter what the purpose, there you can use dependable, long-lasting Vulcabeston that holds tight year after year of the most racking service. The long-fibre asbestos body of Vulcabeston forms a full-fitting gasket that stands up under the extremes of pressure, temperature, moisture and corrosion.

Standardize on Vulcabeston. Stock your storeroom with "The Universal Packing." We would be pleased to furnish samples upon request.

THE JOHNS-PRATT COMPANY **Hartford, Conn., U. S. A.**

The dependable "character"
of Dominion Rubber System Hose
results from its ability to meet exacting conditions.

INDUSTRY is the stern parent of improvement. Twenty years ago the making of rubber hose was in its infancy; to-day it has become an art with us.

Two reasons account for the selection of Dominion Rubber System Hose by most Canadian industries: first, because its performance is a tangible buying guide; and second, because our manufacturing department keeps abreast of industry's most exacting demands.

Dominion Rubber System Hose for Industrial Use

Is designed for every requirement, whether it be for conveying liquids, gases, oils, acids or steam at any practical temperature, or pressure. When new conditions crop up, we produce special types to meet them. The fact that we do create new types for the Canadian market is evidence that Dominion Rubber System Hose measures up to the requirements of Canada's largest hose users.

Our catalog is a useful and convenient reference in selecting the exact type of hose for your requirements. It pictures and describes the complete line and gives the service conditions for which each type is designed. A copy will be sent on request from our nearest service branch.

Opening is Larger than Corresponding Pipe

There is nothing to interfere with the unrestricted flow of passing blow-off sediment when your boilers are equipped with the Yarway (formerly the Simplex) Seatless Blow-Off Valve. The absence of seats and discs, together with the large, smooth port, not only provides smooth passage for the blow-down, but also eliminates troubles met in other valves by the cutting and scoring of scale and grit.
Try one for 60 days, subject to return. When writing, state size of line and whether screw or flange, angle or straightway.

Learn the Good Points of Other Yarway Products

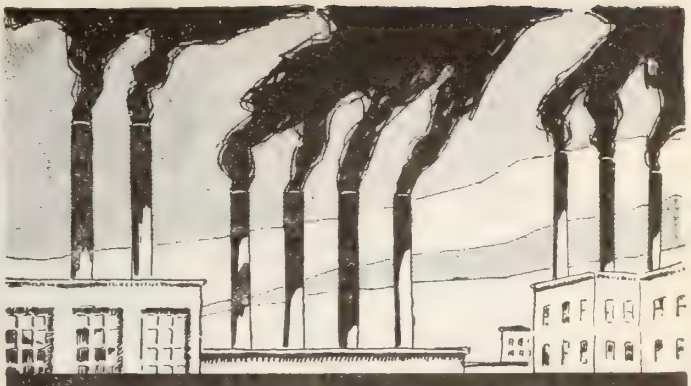
YARWAY
SEATLESS BLOW OFF VALVE
formerly the SIMPLEX

Operation

In closing valve, shoulder "S" on plunger "V" engages the loose follower gland "F," compressing packing "P" above and below the port, making an absolutely tight valve.



GET THE MAXIMUM POWER FROM THE FUEL YOU USE

The fundamental purpose of the boiler setting and the refractory lining is to keep the furnace heat in and the cold air out. Cold air inleakage checks the fire, cools the gases before combustion is complete and sends a large percentage of the heat units of your coal up the chimney.

Separate fire bricks are little more than in place with fire clay when the heat begins to move them.

BETSON'S
REG U S TRADE MARK PAT OFF
PLASTIC FIRE BRICK

should be used to form in place a one-piece, jointless, monolithic furnace lining, including front arch and walls, side walls, bridge walls, combustion chamber and back arch, if any. Also, gas tight baffles should be formed of these same materials. Then you will not only be getting the most out of your fuel, but you will cut your repair bills to the minimum and will avoid the delays and shut downs too often necessary with other types of boiler furnace linings and baffles.

We have an interesting and instructive pamphlet dealing with the uses for Betson's Plastic Fire Brick. Write for it.

The main drive in the mill of Gloucester Lumber and Trading Co., Bathurst, N.B. Goodyear Extra Power Belt still in use after 5 years' service.

Master Belts of Industry

Goodyear has solved the problem of belting the great main drives of industry—the backbone of production.

Experience, in a thousand Canadian plants, says Goodyear Extra Power Belts.

Because these belts are *strong*—with the strength of properly selected fabric, every thread perfect.

Yet *flexible*, hugging pulleys, taking advantage of every inch of pulley surface. Flexible because in Goodyear Extra Power Belting high-grade rubber is forced through and through the fabric in generous quantities. Every strand is cushioned in it. No stitching to stiffen or weaken the belt. No separation of plies.

Its *friction* surface grips, even through dampness or dust. No slipping with Extra Power. No need for extra tight belts, pulling pulleys out of line. No need for belt dressing. No lost power.

The testimony for Goodyear Extra Power on main drives is very complete. For instance:—

The Norfolk Milling Company, of Simcoe, writing about their main drive belt, purchased a year ago, say:—

> *"Has been in continuous operation for one year, and has not stretched nor given us the slightest bit of trouble."*

There are many others—some selected at random are:—

Swedish Crucible Steel Company, Ltd., Windsor, Ont.
Dominion Sugar Company, Ltd., Chatham, Ont.
Dominion Forge and Stamping Co., Ltd., Walkerville, Ont.
Page Wire Fence Company of Canada, Ltd., Walkerville, Ont
Echo Flour Mills, Ltd., Gladstone, Man.
P. Burns Company, Ltd., Edmonton, Alta.
Hollinger Consolidated Gold Mines Co, Ltd., Timmins, Ont.
Dome Mines Company, Ltd., South Porcupine, Ont.
Burrard Saw Mills, Ltd., Vancouver, B.C.
Silverton Lumber and Power Company, Ltd., Silverton, B.C.
Woodstock Electric Railway Light and Power Company Ltd., Woodstock, N.B.
Gloucester Lumbering and Trading Company, Bathurst, N.B.
Amherst Foundry Company, Ltd., Amherst, N.S.
Hull Iron and Steel Foundries, Ltd., Hull, Que.
Quebec Graphite Co., Ltd., Buckingham, Que.

The complete story of Goodyear Extra Power Belts on main drives is interesting. There are facts about other types of drives just as important to you. Let a Goodyear belting man call and talk to you. No obligation. Just phone, wire or write the nearest branch.

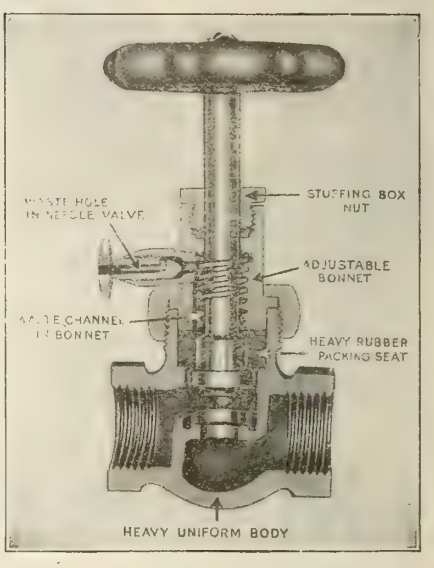
EXTRA POWER BELTING

"The Valve O'Nine Points"

THERE are nine outstanding features of the "EMCO" Composition Disc Valve — plainly shown in the accompanying illustration — which in themselves are sufficient reasons why this valve is superior to any other.



Cross Section "EMCO" A840 Composition Disc Valve

Combined with these

there is superiority of strength, durability and workmanship which is the outstanding quality of every "EMCO" product.

Registered in the following Provinces as follows:

Globe Valve A840

British Columbia	**No. 2590**
Alberta	**" 1102**
Saskatchewan	**" 2365**
Ontario	**" 1755**

The design is approved and registered in the Provinces of the Dominion by Inspectors of Steam Boilers for a pressure of 175 pounds.

Made of the best Bronze Metal, each Valve is subjected to a thorough hydraulic test before it leaves the factory.

We can make prompt deliveries. Write for prices, etc.

LINCOLN ARC WELDING

Every Factory Can Use Lincoln Electric Welding

Special Equipment for Hurried Calls

A LEAKY boiler is not a common occurrence in most plants. Sometimes a batch of castings turn out defective—but not often. Shaftings and other pieces of equipment break and become worn—but only occasionally.

But When Such Things Do Happen

Isn't it rather comforting to know just where to turn—so that you won't have to face a prolonged shut-down—or lose valuable production—or waste valuable equipment.

Lincoln Electric Welding is faithful in such cases. It repairs boilers quickly and permanently—just as it joins together steel sheets, plates, bars, angles, tubes, etc.

You can have a special portable outfit come to your door—install your own Lincoln Welder or send your work to our welding plant.

But there is one sure way to find out exactly what you can do and save with Lincoln Electric Welding.

Get in touch with us. Phone, write or wire for particulars.

WILLIAMS' SUPERIOR DROP-FORGED CLAMPS

THERE'S a Williams' Clamp for every purpose.

If it's extreme strength and heavy service—Williams' "Vulcan" line provides both.

11 sizes, 3/4 to 12½ inches capacities.

If it's general utility—without need for maximum strength—Williams' "Light Service" line will fit the case, 8 sizes, 2 to 12 inches capacities.

If it's stability and utility—medium service—Williams' "Agrippa" line offers the solution. 7 sizes, 4 to 18 inches capacities.

If it's Tool Room work requiring comparatively small openings of jaws — Williams' "Vulcan" Tool Makers' line should be chosen. 4 sizes, 1 to 4 inches capacities.

All are made of a special, high-grade steel. After forging they are submitted to a refining process, or "heat treatment," which increases their stiffness and strength and reduces the liability of springing.

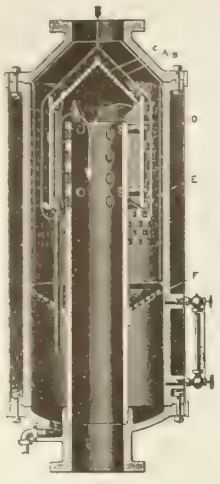
III IMPORTANT THINGS
TO CONSIDER ABOUT
A SAPARATOR



I. THE PLAN—Is it sensible, will it work, no matter how large the Separator or how well made?

II. THE SIZE—Is it big enough regardless of plan, will it hold a good dose of water?

III. THE CONSTRUCTION—Is it strong enough, are flanges heavy, how will it look by the side of a nicely finished engine? Send for catalog and note these points in

DURABLA
TRADE MARK REGISTERED

STRENGTH—GOODNESS—QUALITY

Performance Facts of Durabla Gasket Material

Tight joints are made and maintained by DURABLA under the following severe services and conditions:

Steam:	275-300 lbs. pressure; 275°-300° superheat.
Oil:	Pressure still joint re-made over 160 times.
Gasoline:	Cylinder heads of gasoline engines and pumps.
Acids:	All acids that can be carried in pipe lines.
Water:	Equally satisfactory with temperature of 40° or 210° F., at any pressure.
Ammonia:	Both absorption and compression systems of refrigeration.
Air:	Air lines and cylinder heads of compressors—all types.

One Standard material for all gasket work—Sold on a Service Basis

DURABLA is sold in sheet or gasket form and the trade mark is stamped all over the material.

Do You Throw Away a Faucet When the Washer is Worn Out?

Of course you don't—you simply put in a new washer, costing but a few cents.

It is the same with a Pratt & Cady Renewable Asbestos Disc Globe Valve. When the disc wears out you simply put in a new one at about 10% of the price of an entire new valve.

That saves buying a new valve, also the time and cost of tearing the valve out of the line. Without removing a P. & C. Renewable Valve from the pipe line, a new disc can be inserted in a few minutes.

Try a few Pratt & Cady Renewable Disc Globe, or Renewable Seat Gate Valves and prove to yourself that they will reduce your valve maintenance cost to a mere fraction of your present cost.

Made in Iron and Bronze in all standard sizes for every service.

Write for Valve Book To-day.

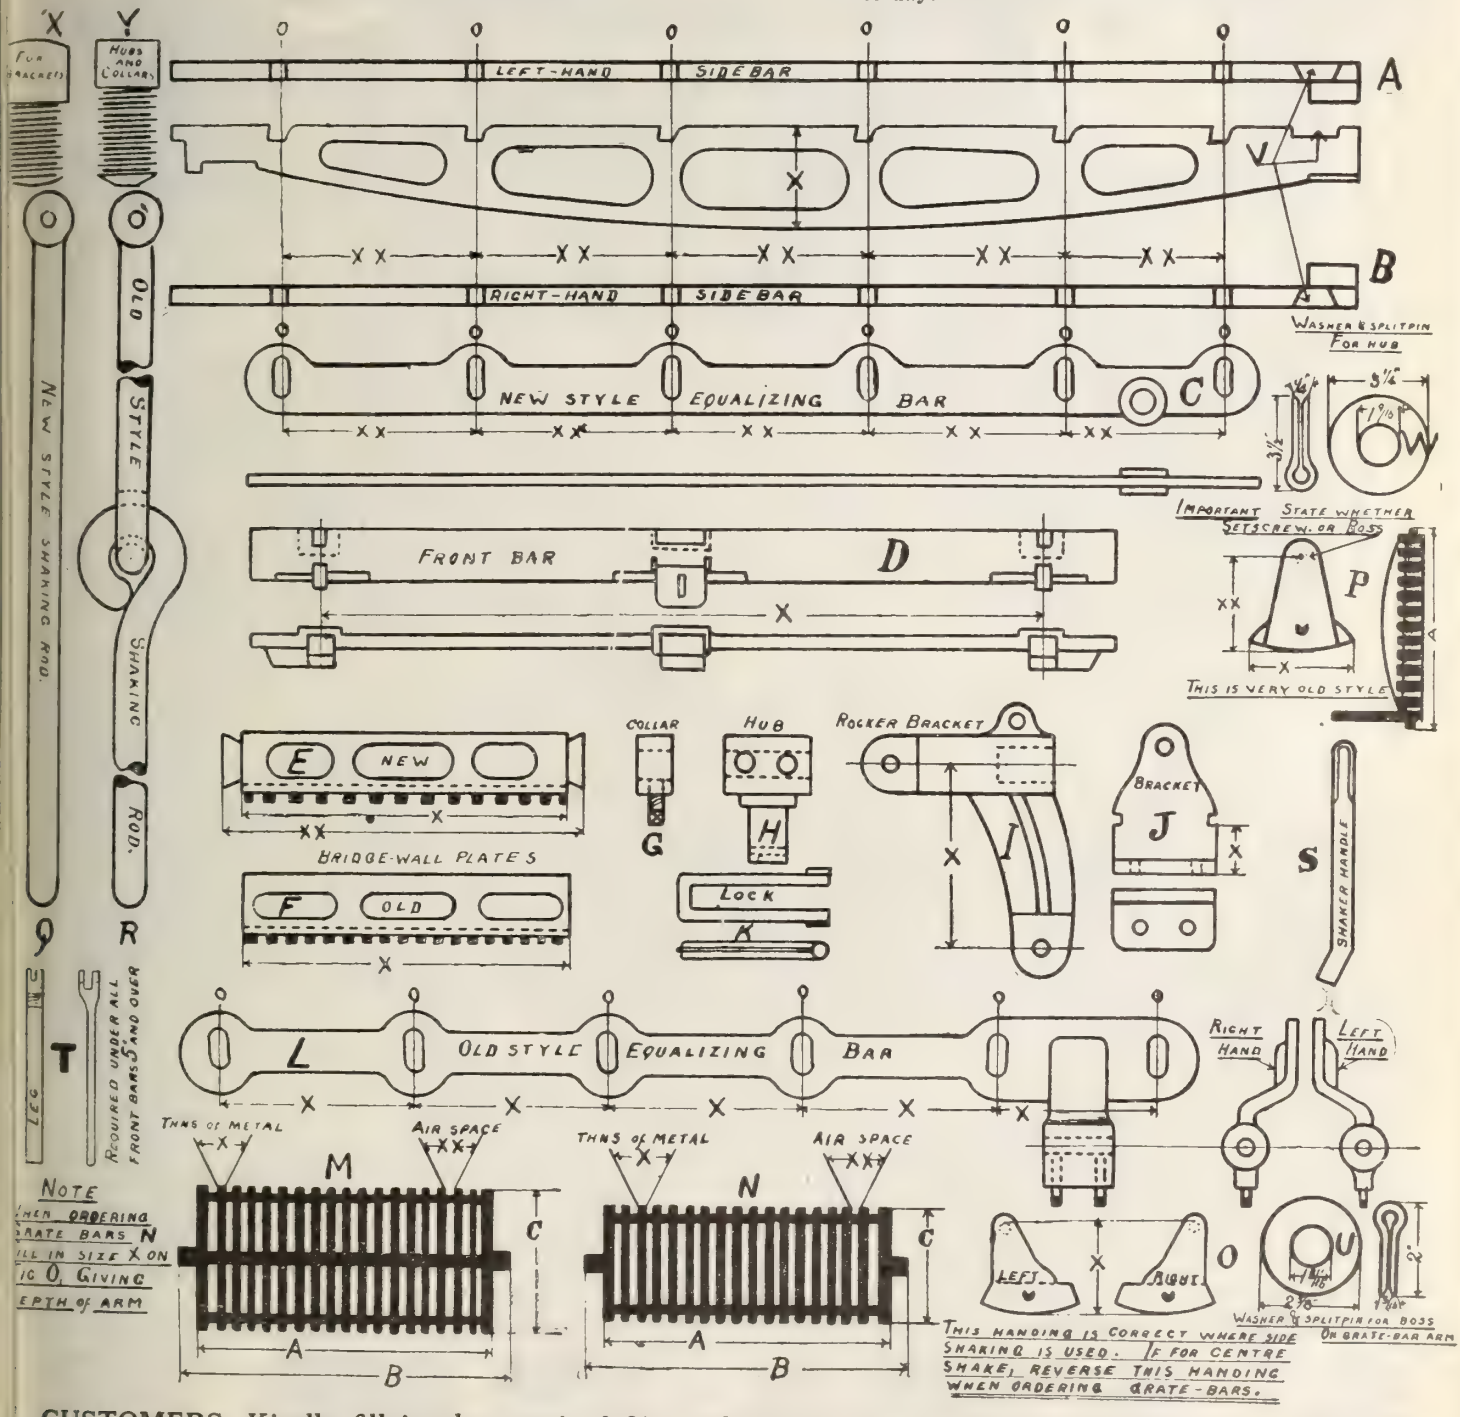
Mount this Chart of "Cyclone" Grate Bar Parts

On Cardboard

You should find this chart helpful when ordering piece parts of our famous "Cyclone" Shaking and Dumping Grates. Keep it handy.

Engineers and plant owners unacquainted with the "Cyclone" Grate and the service we give, **write us to-day.**



NOTE
WHEN ORDERING GRATE BARS N FILL IN SIZE X ON FIG O, GIVING DEPTH of ARM

THIS HANDING IS CORRECT WHERE SIDE SHAKING IS USED. IF FOR CENTRE SHAKE, REVERSE THIS HANDING WHEN ORDERING GRATE-BARS.

CUSTOMERS: Kindly fill in the required Sizes when ordering Parts and it will greatly facilitate the dispatch of same. When ordering Parts for grates N, which is the old style 8" centres, and all sizes under, kindly order as far ahead of date required as possible, as we do not carry large stock of 8" centres and under.

Cut out this chart and keep for reference, or write us and we will send you a copy free.

Tuyeres
3
Fuel-retarding Mechanism
LACLEDE
A BUSINESS INSTITUTION

THE STOWE STOKER

EMPLOYING MECHANICAL DRAFT

Its fundamental principle is a conveyor feed, positive in action from coal-hopper to ash-pit.

One feature of the Stowe Stoker is the provision which brings about

Low Combustible in the Ash

The stationary tuyeres (2) terminate at their lower end in the retarding bars (3). These bars are automatically raised and lowered. In their lower positions the ash is positively carried onward toward the ash-pit by the conveyor grate elements (1), and in their raised position the ash is just as positively held back in the furnace.

The relative duration of these two alternating influences can be controlled from the front of the stoker, to produce any desired thickness of fire at the ash discharge end of the stoker, and to accommodate either high or low ash coals.

These retarding bars hold the nearly spent fuel in the furnace, subjecting the last traces of combustible for a considerable period to the influence of the furnace temperatures, and to the moderate air allowance supplied by the full blast pressure of the wind box.

The result: *A new standard for low combustible in the ash.*

We also manufacture the L-C Chain Grate Stoker—the Natural-Draft Type for Higher Volatile Coals—Dominant in this Field Today.

DEPARTMENT OF LABOUR
Ontario Government

Minister: Hon. W. R. Rollo — Deputy Minister: W. A. Riddell, Ph.D.

NOTICE TO STATIONARY AND HOISTING ENGINEERS AND STEAM PLANT OWNERS

Everyone operating a **Stationary** steam plant of 50 B.H.P. or over, and everyone operating a **Hoisting** steam plant working at a pressure of 20 pounds or over, irrespective of horsepower and used for hoisting in structural operations or excavating purposes, in the Province of Ontario, must hold a certificate from the Board of Stationary and Hoisting Engineers. Application forms will be forwarded upon request.

After January 1, 1920, all stationary steam plants in the Province of Ontario must be registered with the Board of Stationary and Hoisting Engineers. Application forms will be forwarded upon request.

All applications should be mailed to the Chairman of the Board. W. C. McGhie, Department of Labour, 15 Queen's Park, Toronto.

NOTICE TO MANUFACTURERS, DEALERS AND USERS OF STEAM BOILERS

All steam boilers built in, or entering, the Province of Ontario, and boilers exchanged or repaired, are subject to Government Inspection as prescribed in the Steam Boilers' Act, 3 George V., ch. 61.

Before any work of repair or alteration is commenced on any boiler, notice must be sent to the Department stating the nature and extent of the repairs or alterations proposed to be made. If the Chief Inspector should consider such repairs or alterations of an extensive character, the boiler must be inspected in accordance with the Regulations by an Inspector authorized under the Act.

All communications should be addressed to the Steam Boiler Branch, Department of Labour, 15 Queen's Park, Toronto. D. M. Medcalf, Chief Inspector of Steam Boilers.

Plant of the Oil Well Supply Co., Pittsburgh, Pa.

Upper Run Over Bunkers

Handling Ashes on Lower Run

Saving Labor And Expense With A Jeffrey Pivoted Bucket Carrier

At the plant shown above, an 18" x 24" Jeffrey Pivoted Bucket Carrier completes the cycle of automatically handling coal from bottom dump cars to stokers with a minimum of labor.

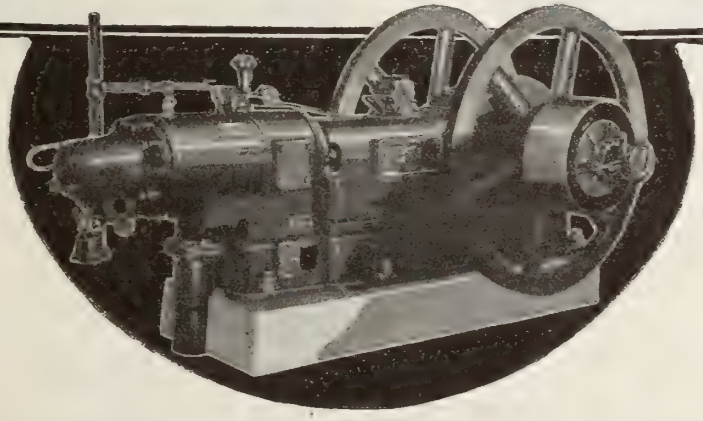
This Jeffrey Carrier has a 57 foot lift and a horizontal run of 68 feet. Handles both coal and ashes, coal being received from a roll crusher.

Catalog No. 210-3 fully illustrates and describes the Jeffrey Pivoted Bucket Carrier. Write for Catalog.

The Jeffrey Mfg. Co., *Canadian Branch and Warerooms,* **MONTREAL**

The Fuel for Economical Power

Performance records are available showing the dependability and operating economy of Giant Oil Engines under service conditions similar to yours.



Giant Semi-Diesel Oil Engines are built in capacities from 12 to 200 H. P., both single and duplex types.

OIL is readily procurable and its cost for fuel is low. And low-cost fuel oils are utilized most successfully by Giant Semi-Diesel Oil Engines —because:

Giant Oil Engines are of advanced, highly standardized design—simple and rugged in construction. They have no valves, magnetos, carburetors, wiring or other complicated devices to render dependability uncertain.

Their automatic regulation prevents waste of fuel and power, and largely eliminates the human factor in engine operation.

Power costs of ½ to ¾ cent per horsepower hour are common amongst "Giant" users.

Oil as your standard fuel and Giant Semi-Diesel Oil Engines utilizing it will economize power in your plant. Write for bulletins.

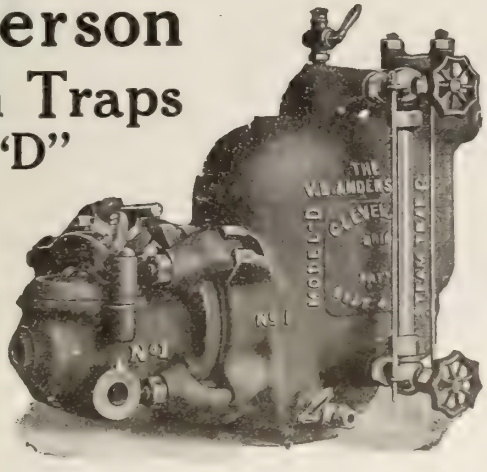
Anderson
Steam Traps
Model "D"



Stays Tight

The Anderson Model D Steam Trap is positive proof against break-downs due to accumulated moisture in engine cylinders and turbine castings. The Anderson can be counted upon to deliver **dry steam** under all operating conditions.

From the day you install an Anderson Model D steam Trap it will remain tight.

Every part is machined to solid gauge. Self-contained strainer and self-contained by-pass are Anderson features. The simple design gives complete accessibility to every part.

You can't afford to tolerate a trap that doesn't drain, or lets live steam through.

Our catalog contains a full description of the Anderson—Write for it to-day.

Get Clean Water for Your Condenser Intakes

by installing

Link-Belt Water Screens

LINK-BELT Traveling Water Screens automatically remove the debris from the water and insure a steady supply of clean water to the condensers at all times. They are self-cleaning, require little attention and can easily be adapted to almost any intake system.

Let our experienced engineers investigate your system and make recommendations. Write for catalog.

Clearance Sale of High Grade Technical Books

FOR several years we have maintained a Technical Book Department, handling high-class books published by various well known publishers. For various reasons we have now decided to discontinue our Book Dept. and in order to clear out what stock we have on hand we offer the following books at prices considerably lower than the regular selling price. Each item represents high quality at bargain prices. These books will not last long—first come first served. This is a fine opportunity to add to your technical library.

Title of Book.	Name of Author.	Binding	Number of pages	Illustrated	Price
Electric Chemistry	G. W. Cravens	Cloth	132	Yes	$1.10
Hawkins Electric Dictionary (Best)	N. Hawkins	Leather	537	No	2.50
Electricity Simplified	T. O. Sloane	Cloth	172	Yes	.85
Electrical Motor	E. E. Burns	Cloth	197	Yes	1.25
Starting a Printing Office	R. C. Mallet and W. H. Jackson	Cloth	90	Yes	1.45
Half Tone Process	J. Verfasser	Cloth	378	Yes	....
Modern Printing Machinery	Wilson & Gray	Cloth	455	Yes	4.50
Manufacture of Paper	R. W. Sindall	Cloth	275	Yes	1.50
System for a Medium Size Printing Shop	C. V. Simmons	Paper	26	Yes	.50
Embossing	R. H. Dippy	Paper	12	No	.25
Patents, Inventors, Advisers	Marion & Marion	Cloth	170	Yes	.75
Machinists' Guide	Wm. Rogers .	Cloth	323	Yes	1.50
Mechanical Refrigeration	S. Sydney .	Cloth	70	Yes	1.25
*Stationary Engineers.	Is in sets of three volumes.				
Boiler Construction	F. B. Kleinhans	Cloth	422	Yes	2.50
Audels Answers on Practical Engineering	Harris & Associates	Cloth	254	Yes	.75
Gas and Oil Engines	L. E. Brookes	Cloth	192	Yes	.85
Ford Car	V. W. Page	Cloth	288	Yes	....
New Catcehism of the Steam Engine	N. Hawkins	Cloth	429	Yes	1.50
Mechanical Arts Simplified	D. B. Dixon	Cloth	497	Yes	1.25
Setting Valves of Canadian-made Engines	G. C. Keith	Paper	31	Yes	.25
Change Gear Devices	O. E. Perrigo	Paper	81	Yes	1.25
Factory Power Costs	J. G. Branch	Paper	43	No	.75
The Field Engineer	Unable to find book in stock				1.50
Power Stations and Transmission	G. C. Shand	Cloth	84	Yes	.85
Liquid Air	T. O. Sloane	Cloth	365	Yes	2.10
New Guide Book to the Local Marine Board	C. M. Swainson	Cloth	545	Yes	1.30
Modern Machine Shop Tools	W. H. Van Dervoort	Cloth	552	Yes	3.00
Locomotive Catechism	R. Grimshaw	Cloth	432	Yes	1.50
Locomotive Breakdowns	G. L. Powers	Cloth	244	Yes	1.25
Modern Ironmonger		Cloth	341	Yes	1.00
Gas Engine Troubles	J. B. Rathbun	Cloth	448	Yes	1.00
Combustion of Coal and Prevention of Smoke	Wm. M. Barr	Cloth	347	Yes	1.25
How to Run Gasoline Engines	C. Von Culin	Paper	144	Yes	.50
Engineers' Library	W. H. Wakeman	Paper	Different No. in each	Some are	.25
Elements of Machine Design	J. H. Barr	Cloth	446	Yes	2.00
Hawkin's Indicator .	N. Hawkins	Cloth	73	Yes	.75
Gas Engine Construction	Parcell & Weed	Cloth	304	Yes	2.00
Aids to Engineers Examinations	N. Hawkins	Cloth	222	No	1.50
Mechanism of Mechanical Movements	Unable to find book in stock				2.00
Pattern Making	Ritchey & Monroe	Leather	222	Yes	1.25
Machine Design	E. L. Wallace	Cloth	157	Yes	1.25
Foundry Work	B. L. Gray	Cloth	196	Yes	1.25
Forging	J. Jernberg	Cloth	131	Yes	1.25
Tool Making	E. R. Markham	Leather	288	Yes	2.00

***These books are in sets of 3 volumes to a set. There are eight sets in stock. The price of which are $4.50 per copy of $12.50 per set.**

Above prices includes postage. Cash must accompany order as at the reduced prices quoted accounts cannot be opened. Remit by express or P.O. money order or by registered letter.

Plibrico is molded into place; needs no forms and H requires minimum time and labor.

PLIBRICO Makes Air Tight Furnace Linings

Air leaks in furnace lining joints, boiler settings and baffles are the greatest preventable losses in a boiler plant. No argument should be necessary to establish the fact that **An Air Tight Furnace Lining** is a great fuel economizer.

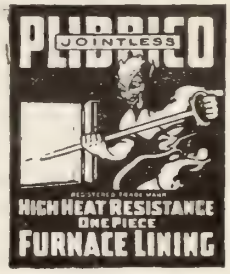
Shipped in steel containers only. Warehouse stock carried in principal cities for immediate delivery.

Send for book on furnace building.

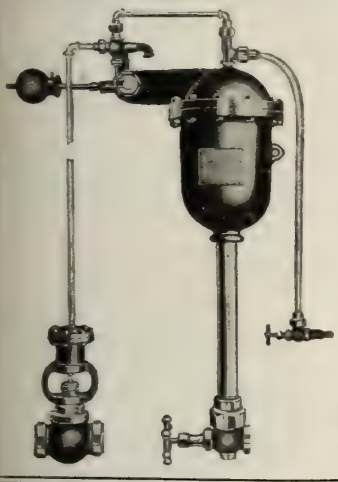
JOINTLESS FIRE BRICK CO.

Offices and Factory, 1130-1150 Clay St., Chicago, Ill.

Beveridge Paper Co., Ltd., Montreal. Shell Bar Boico Supply Co., Ltd., Toronto, Canadian Representatives.



Trade Mark
Reg. U.S. Pat. Office.



They Never "Forget"

VIGILANT FEED WATER REGULATORS

are always on the job every minute of the day, constantly making sure that the exact amount of water is being fed into the boiler to keep the gauge at middle point. And this saves coal—don't forget that very important point. Let us explain how.

Write for full information to-day.

MORRISON

Even, Low Pressure Maintained by J.M.T. Reducing Valves

A sudden change in the low pressure demand, or variations in flow and pressure on the high pressure side have no effect on the constant low pressure maintained.

The J. M. T. does all that a pressure-reducing valve can do. Since its introduction there has been no "problem" of pressure reduction of air and steam.

Method of Operation

J. M. T. Reducing Valves are controlled by the variation of the reduced pressure acting through the port A, (shown in the cross-section) on the diaphragm 6. This diaphragm is resisted by the spring 4, which is adjusted to the desired pressure. This construction allows the diaphragm to be raised by an increase of the reduced pressure and forced down by the spring 4, when the reduced pressure is decreased.

The auxiliary valve 8 is held in contact with the diaphragm by the auxiliary valve spring 14, and moves up and down freely with the diaphragm. As soon as valve 8 is open steam passes through into port B and under piston 11. By raising piston 11 main valve 19 opens against the initial pressure, because the area of valve 19 is less than the area of piston 11, steam is thus admitted to the system. When the pressure on the low pressure side reaches the required point, which is determined by the spring 4, the diaphragm is forced upward by the low pressure steam which passes up through the port A to the under side of the diaphragm 6, allowing valve 8 to close, shutting off steam from piston 11. Main valve 19 is now forced to its seat by the initial pressure, shutting off steam from the system and pushing piston 11 down to the bottom of its stroke. Steam beneath piston 11 exhausts freely around the piston and passes off into the low pressure side.

In practice the main valve does not open or close entirely with each slight variation of pressure, but assumes a position which furnishes just sufficient steam to maintain the desired pressure. Piston 11 is fitted with dash pot 12, which prevents chattering or pounding.

These valves can be furnished for ranges of reduced pressure as follows: 5 to 50 lbs., 50 to 140 lbs., 140 to 300 lbs.

Full particulars of these or any other steam specialties will gladly be forwarded upon request.

Class N-SBE Motor-driven Compressor installed by Taylor & Dean, Pittsburgh, Pa. Capacity 147 cubic feet per minute.

An ideal unit for moderate air power needs

CHICAGO Pneumatic Short-Belt Motor-Driven Air Compressors are ideal units for the small air power plant. Their compact construction economizes space. The short-belt drive with idler pulley prevents belt troubles

These units embody the same advanced principles of design and construction as the larger Chicago Pneumatics—Simplate Indestructible Flat Disc Valves, automatic regulation and lubrication, great rigidity, liberal bearing surfaces—all insuring more power with less waste; longer service with less upkeep.

Electric motor, steam and belt-driven types of these units are usually available from stock at the Company's branches listed below. Capacities 69 to 1197 cubic feet per minute.

Ask for Bulletin.

WORTHINGTON
DOUBLE SUCTION
TURBINE PUMP

Worthington Centrifugal Boiler Feed

TO satisfy the need for a centrifugal boiler feed pump that is free from end thrust, Worthington offers their Double Suction Turbine Pump for boiler feed.

Worthington has designed and built into this centrifugal type pump a distinctive hydraulic balance port which inhibits end thrust even when the pump becomes old. And this continuously good, long service has made Worthington Double Suction Turbine Pump leader in its field and worthy representative of the engineering skill and constructive ability of the 80 years old Worthington organization.

This pump is one of the varied Worthington line of power plant apparatus that has successfully satisfied over 200,000,000 boiler horse power since 1840.

PROPERLY SIZED COAL IS ESSENTIAL FOR INDUSTRIAL AND RAILWAY OPERATION

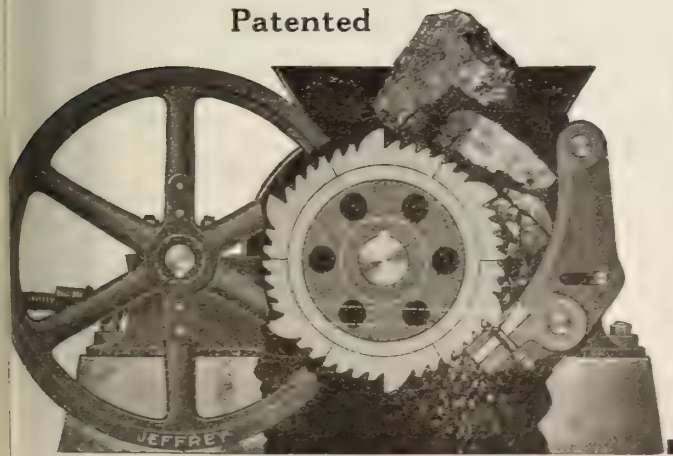
IN old days fuel problems were not given the attention demanded at present. With the installation of automatic stokers in Boiler Houses and on Railway Locomotives and limitations of size of lumps for hand firing, it is necessary that Industrial Power Houses and Railroad Coaling Stations be prepared to supply the proper sizes of coal. A Jeffrey Single Roll Crusher with its easy adjustability to give various products meets this condition.

What a

Jeffrey

Single Roll Crusher Installation Means to You

Patented



Makes you independent of the regular supply of screenings.

Permits the use of Run-of-Mine or Lump Coal in your stokers.

Enables you to buy lump coal of proper quality in place of inferior screenings.

Produces the most efficient sizes of coal for stoker use.

Saves money—proper fuel means economical operation.

SHIPMENTS FROM STOCK

Write for Catalog No. 141-4, fully illustrating and describing the Jeffrey Single Roll Crusher.

Capacity Production

EVERY manufacturer wants capacity production; he wants every ounce of power and work from his machinery. Volume of production is largely a matter of steady, uninterrupted work, which means that the machinery must be maintained at maximum efficiency.

To give this continuous, efficient service, machinery must be properly lubricated. Correct lubrication is inseparable from the economical operation of machines and power equipment; it is a big factor in profitable manufacturing and *you cannot afford to use any but the best lubricants in expensive machinery.*

Imperial Lubricants are well known for their high, uniform quality. They are graded for every type of machine and every moving part. They have been tested and proved under actual service conditions to be of superior fitness for the work for which each is designed.

If you have lubrication problems or difficulties, write to our Imperial Lubrication Engineers. They will gladly study your problems and submit recommendations free of charge or obligation.

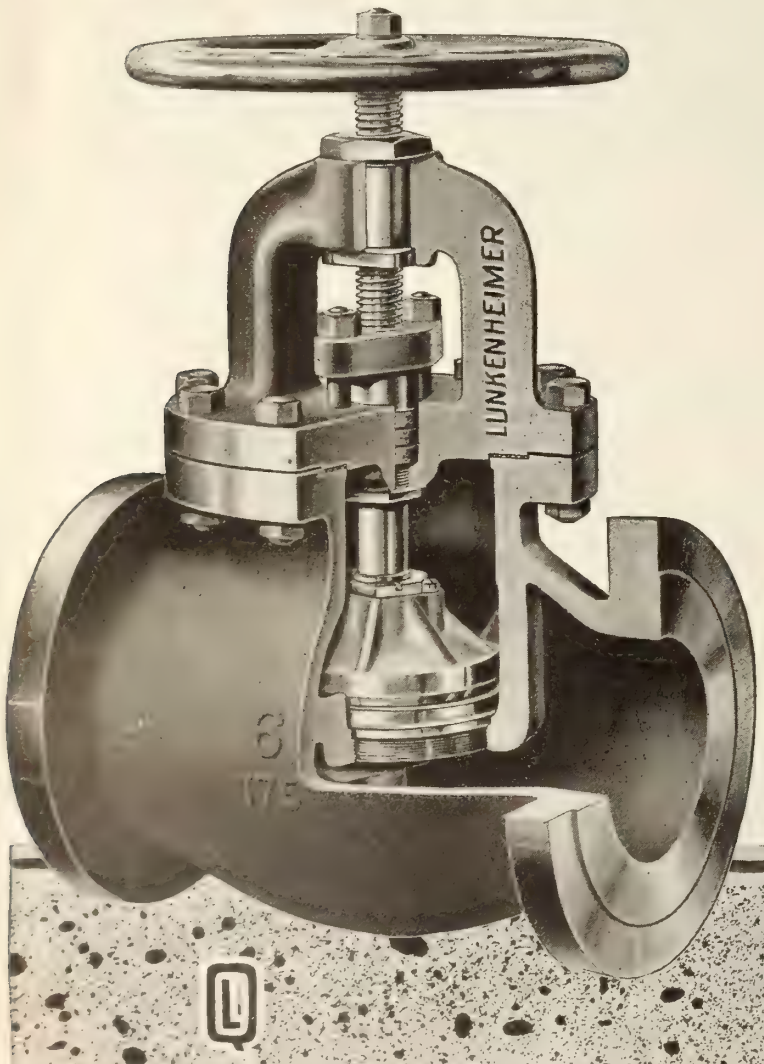
-lasting satisfaction-

LUNKENHEIMER

IRON BODY BRONZE MOUNTED

GLOBE, ANGLE, CROSS & CHECK VALVES



give lasting satisfaction in service. Their design, extreme strength and durability due to the high quality materials used, and the Lunkenheimer system of test and inspection which they undergo, insure safety and maximum valve service.

Lunkenheimer "Valve-iron" is close grained and has a tensile strength far in excess of the iron used in the average valve. The trimmings are made of Lunkenheimer "Valve-bronze," a material possessing extreme wear resisting qualities.

The spring seat, peculiar to Lunkenheimer valves, will compensate for any slight distortion which may be caused by temperature change or pipe strains. The seating surfaces are re-grindable and all the parts renewable.

For high temperature service these valves can be supplied with trimmings made of Lunkenheimer "Valve-nickel"

All standard sizes, in three weights, for working steam pressures up to 125, 175 and 250 pounds.

Specify LUNKENHEIMER Iron Body Valves and insist on their installation.

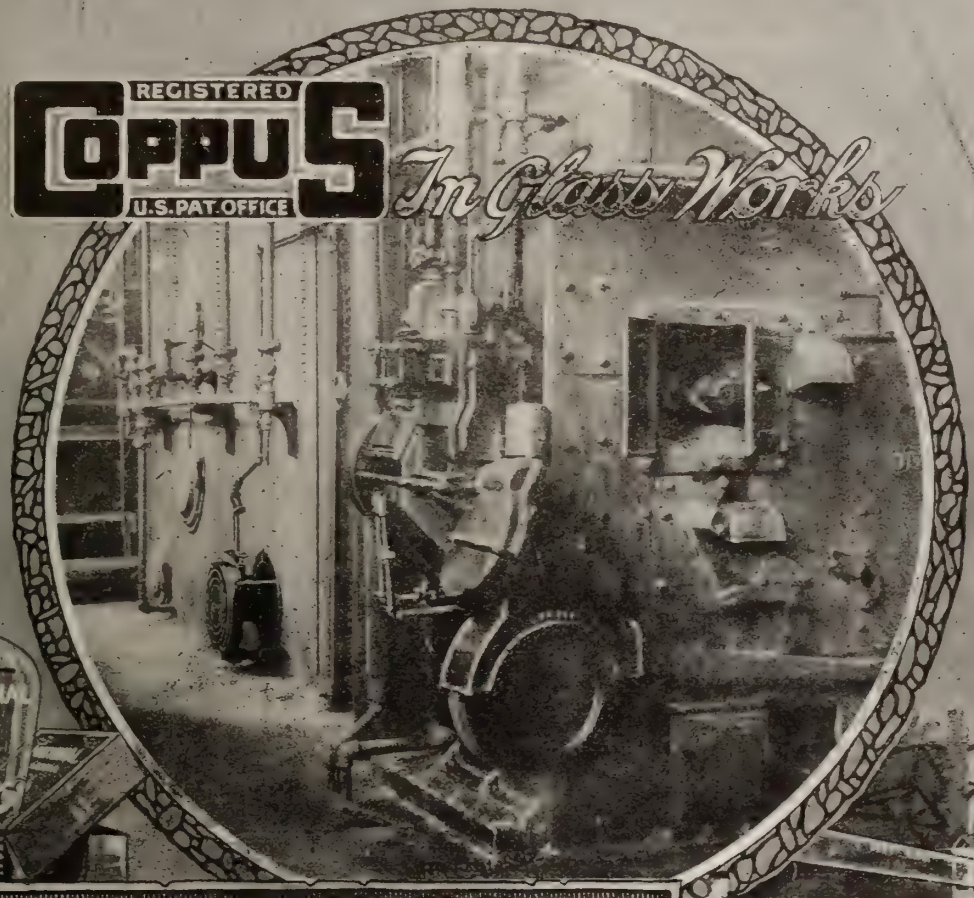
REGISTERED COPPUS U.S. PAT. OFFICE

In Glass Works



In the Glass Division Power Plant of the National Lamp Works out in Cleveland, Ohio, they burn gas coal screenings and producer tar—difficult fuel to burn economically. Yet with the 4-18" COPPUS Turbo Blowers which they operate, full steam pressure is maintained in their 4-250 H.P. Stirling Boilers—and cheap fuel is efficiently furned. Without these Blowers, one of which is shown above, additional boilers would have been necessary last fall. With their aid, however, the heavy plant load is easily handled.

Before the National Lamp Works installed COPPUS Blowers a careful investigation satisfied them that for efficient operation, low steam consumption, and sturdy dependability, COPPUS Blowers stand in a class by themselves. And after practical proof that COPPUS Blowers are all that is claimed for them, Mr. Bretz, Plant Superintendent, expresses himself as "highly pleased with them." In the National Lamp Works, as in thousands of plants in every industry, COPPUS Blowers have proved profitable investments.

Why not find out exactly how and why "COPPUS EQUIPMENT CAN SAVE YOU MONEY." Write us and our engineers will help you solve your combustion problems. If you haven't a copy of Blower Catalog write for one to-day.

TAG TAG TAG TAG

Maximum and Minimum
the Same
Under TAG Control

The best way to conserve coal is to supply the power needed and no more.

It's no economy to supply too little power, and the balance between too much and too little is hard to strike by hand valve manipulation.

The TAG Self-Operating Pressure Controller does it for you. Set it and forget it; it works automatically; it needs no care or attention.

On your steam, oil, air and water lines there is never so much as a half-pound of pressure difference between maximum and minimum with a TAG Controller on the job.

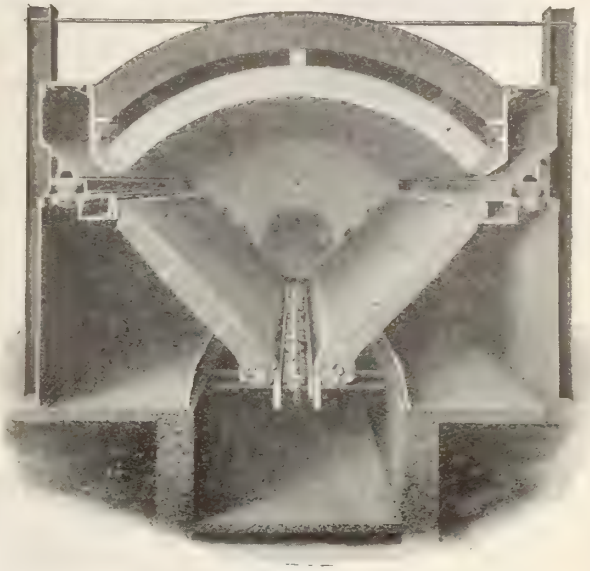
MURPHY AUTOMATIC FURNACES



STOOD the Test of Time

The Murphy Furnace is the pioneer among stokers. It is one of the oldest—and one of the best; 37 years of successful operation—and still going strong. To-day over 6,000 boilers are fired by Murphy Furnaces.

Remember that during that time a great many manufacturers have sprung up and died. Time tells—the principle must be sound—the operation successful.

Our engineers have gathered a store of useful information. The Catalog HM-5 is yours for the asking.

For information on RILEY UNDERFEED STOKERS for large boilers, see last month's advertisement or send for RILEY STOKER Catalog "HR-5."

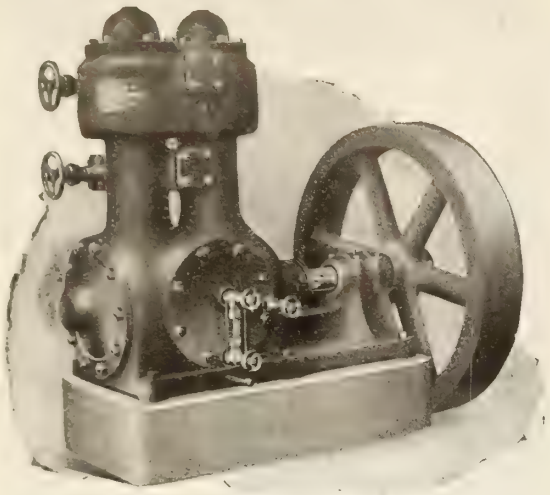
Mechanical Refrigeration



Reliable--Beneficial

THE many benefits common to all users of MECHANICAL REFRIGERATION, should make it a valuable adjunct to your business.

The uniform temperatures it provides have a better holding effect on the product in storage than ice, because the temperature produced by ice is not uniform, varying with the amount of ice in the refrigerator.

MECHANICAL REFRIGERATION permits the maintenance at all times of any temperature desired in the refrigerators or cold storage rooms, whereas you can not always get ice just when you need it, and a delay of a few hours often means a loss through deterioration of the product in storage.

If interested in MECHANICAL REFRIGERATION, a request for information and prices will receive our prompt attention.

DURABLA

For Better Commutation

on Motors, Generators and Rotary Transformers

USE

"Le Carbone" Carbon Brushes

Losses through faulty commutation are among the most troublesome with which operators of electrical equipment have to contend—and are often far more serious than is realized. For thirty years the growing use of "Le Carbone" Brushes has been reducing this loss.

The quality of "Le Carbone" Brushes is not only extraordinarily high, but absolutely uniform in each and every grade. Dimensions are accurate, ensuring perfect fit in the brush holders. Composition does not vary from the standard for the grade, so that exactly the same conductivity and co-efficient of friction can be relied upon year after year, so long as "Le Carbone" Brushes are in use.

When the right grade of "Le Carbone" brush is selected (and when we know the characteristics of the machine we undertake to do this) sparking is practically eliminated, and pitting, flash-overs, burnt-out brush holders and commutator wear are unknown. Commutation is perfect, efficiency of the machine is raised, and service is uninterrupted.

If you have a troublesome machine, give us full particulars—try out the "Le Carbone" Brushes we recommend—and return them if they don't give satisfaction.

"Handy" Commutator Stones

Keep commutators in A-1 condition with less trouble and lost time than any other device. They quickly reduce flat spots, high mica, high bars, ridges or other rough spots, removing far less copper than when the commutator is turned, and leaving a smoother surface than can be obtained by fine sandpaper.

Use No. 6 Cutting Stone for preliminary work and No. 25 Finishing Stone for polishing. *Both can be used with machine running at full load.*

Supplied in any size up to 12″ x 12″ x 10″, with handles to suit.

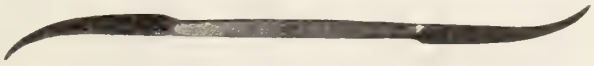
"Handy" Commutator Slotting Files

The part which undercut mica plays in aiding perfect commutation is now generally recognized—and one of the quickest, easiest, cheapest ways to slot a commutator and to keep the mica down is with the "Handy" Commutator Slotting File.

It is tempered to cut mica readily, but to drag as soon as it gets down to the copper, so that even an inexperienced workman can easily tell when he has gone just far enough. The "V" slot leaves the sides protected against short circuits from accumulation of oil and dirt.

Neither brush holder nor armature need be removed. A commutator can be slotted at night or in odd moments of rest, *without any loss of operating time.*

"Handy" Files are both single and double ended.



For extensive commutator slotting we recommend the Aurand Portable Electric Commutator Slotter and for general commutator repairing the Peerless Universal Armature Machine.

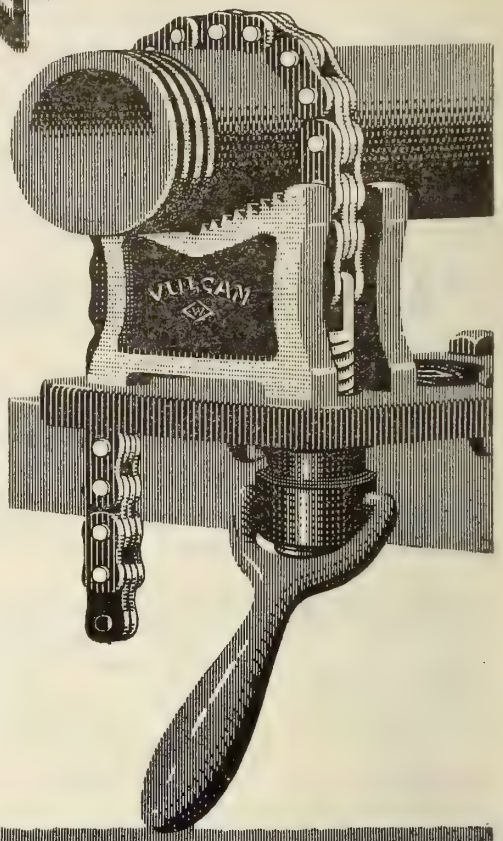
WILLIAMS' "VULCAN" DROP-FORGED CHAIN PIPE VISE



A PIPE vise, like any tool intended for rough usage, should be so designed and constructed that the severe strains and stresses of hard, continuous service cannot cause breakage or failure in operation.

Williams' "Vulcan" Chain Pipe Vises have no weak parts to fail through faulty design. Though they are far lighter and cost less than the conventional cast pipe vise, they are unbreakable. These Vises are made entirely from wrought metal, tested in our Laboratories before use. Each Chain is hand made.

Nothing that engineering experience and technical skill can suggest to improve them is omitted in their manufacture. All are backed by our unconditional guarantee.

Three sizes for ⅛ to 8" pipe. Booklet on request.

Better Jobs— Bigger Salaries

Let These Men Show You How to Get Them

Are you interested in sure and rapid advancement to a really worth while position in one of the best paying professions in the country today? If you are it will pay you well to read this announcement. It tells how you, with or without previous training, can prepare yourself in a short time for an attractive position that insures a lucrative salary and an assured future.

Remember—this profession is a new one—unlike all others, it is still uncrowded—and the demand for trained men far exceeds the supply. That's why your services will be in demand when you have acquired the necessary training. That's why you can count every effort a sure and wonderfully profitable investment.

Easy to Learn— No Experience Necessary

In most professions, to become proficient, long periods of intensive study, followed by years of hard training, are necessary. In this new profession—Combustion Engineering—the necessary training can be acquired in a few short months. Why? Because all the knowledge and experience—all the scientific research and experiments—all the labor and study of seven of America's leading Combustion Engineers have been condensed and classified to such a remarkable extent that what formerly required years of study can now be learned in a fraction of that time.

This training from the very first can be applied to the practical every-day problems of any power plant. At some point in the course you must spend some time in power-plant work if you have not already had the experience. That may prove to be your field or you may make it the stepping stone to an executive position. In either case your services will increase in demand and value as you progress in the training.

America's Leading Combustion Engineers Teach You

On this page are photographs of our educational staff. Probably you know some of these men personally. At least, all or most of them, are known to you by reputation.

Jos. W. Hays is the author. His reputation as a writer on Combustion Efficiency is world wide. In this course he has surpassed himself. Every lesson, every chapter, is written in such an interesting, comprehensive way, that the reading of the course is as pleasant as it is profitable.

Associated with Mr. Hays as reviewing and advisory editors are **I. E. Moultrop, W. L. Abbott, Jos. Harrington, Fred R. Low, David Moffat Myers, Prof. S. W. Parr and Arthur L. Rice.** These names alone are proof positive of the thoroughness and completeness of the course.

Especial attention has been given to make this course easily understood by everyone. It is stripped of all unnecessary technicalities and is written in a way that you can quickly grasp and understand. It is prepared especially for the man on the job—the busy man in office or boiler room who can commence putting his knowledge into practice the moment he starts the course.

Send for this FREE BOOK—TODAY

To enable you to get a better idea of just what this course is—just what it covers—why it is a guide to a better job and a bigger salary—why it enables *you* to cash in on the big salary awards that fall to the Combustion Expert—to make all these things clear to you, we have prepared the book "Opportunities for the Combustion Expert." Send for a copy of this book today. It's free.

Mail the Coupon

Simply fill in the coupon and mail it to us. We'll send you a free copy of "Opportunities for the Combustion Expert" by return mail. Time is valuable. Get started today while the opportunities are greatest. Mail the coupon—Now.

JENNINGS TURBINE VACUUM AND LOW PRESSURE BOILER FEED PUMP

For return line heating systems, dryer exhaust systems in paper mills, or other vacuum work where large percentages of liquids have to be handled with gas the Jennings is without equal. Its distinct advance in principle and design over all other types is the result of many years experience in building turbine vacuum pumps.

The Jennings has two independent turbine units, an air pump and a water pump, combined in one casing, with the impeller of each mounted on the same shaft. The horsepower required to operate this pump is less than half that consumed by any other vacuum heating pump of the same capacity.

We would like to tell you more about the many distinct features of this pump. Write for full information.

Power Plant of the St. Lawrence Sugar Refinery

A Brief Description of the Leading Features of This Montreal Plant, Where Tests on Oil and Coal Fuel Are Being Made

By J. H. RODGERS

THE abnormal large quantities of steam and water that are constantly required for the uninterrupted activities of a sugar refinery, necessitates the continued operation of the power equipment that supplies the many department with these essential elements. The St. Lawrence Sugar Refinery, when operating at capacity will use approximately 5,000,000 gallons of water every 24 hours, including that required for steaming purposes and the working of the sugar-making equipment. The demands upon the power end has been steadily increasing so that the present requirements of the plant approximates 5,000 horse-power.

The new boiler house is designed along the most modern lines, with the coal bunkers located directly above the front end of the boilers. In the new boiler house there are six 400 h.p. Babcock and Wilcox boilers arranged in two batteries of three boilers each. They are all fitted with the Murphy type of automatic furnace, and equipped with Green fuel economizers, one economizer being used for each battery.

In the fall of last year the company, after considerable study and investigation, decided to carry out an experiment in the use of fuel oil to determine its economic value in comparison to coal. In the new boiler house one of the batteries of three boilers was fitted with oil burning apparatus and each battery was made a distinct and separate operating unit, so that accurate records could be made as to the respective efficiencies. In the old boiler house, where four 375 h.p. and two 200 h.p. Babcock and Wilcox boilers are installed, the use of oil has also been adopted on the larger battery, but no attempt is made to carry out a competition test with the coal fired boilers, as the old boiler house is only equipped with the one economizer for the entire six boilers, and likewise the one set of recording instruments. The boilers in the old power house are equipped with the Jones Underfeed stokers and the time required for alterations to the grates and setting, for the use of oil, is much greater than for the Murphy type. In the latter it is possible to change over from oil to coal, or vice versa, in about 48 hours, while changes on the boilers fitted with the Jones stokers would require nearly a week. The feed pumps in the old boiler house are of the Garrison duplex type, outside packed and fitted with regulators. The new boiler house is equipped with Worthington centrifugal feed water pumps. All condensation from the entire plant is returned to the feed water tanks.

In the new boiler house a very close check is being kept on every detail of operation. Each battery is operated as a distinct unit and daily records are kept of the service obtained from each battery. Records are made of feed water temperature, outlet of each economizer, flue gas temperatures, all parts being equipped with thermometers. The boilers are fitted with Ellison draft gages, so that the furnace draft, draft in the combustion chamber over the fires, and the draft loss in the boilers, are indicated immediately to the man in charge, so that the actual furnace conditions are shown at all times, and any variation from ideal working conditions may be seen and corrected before serious loss is effected.

NEW BOILER HOUSE.

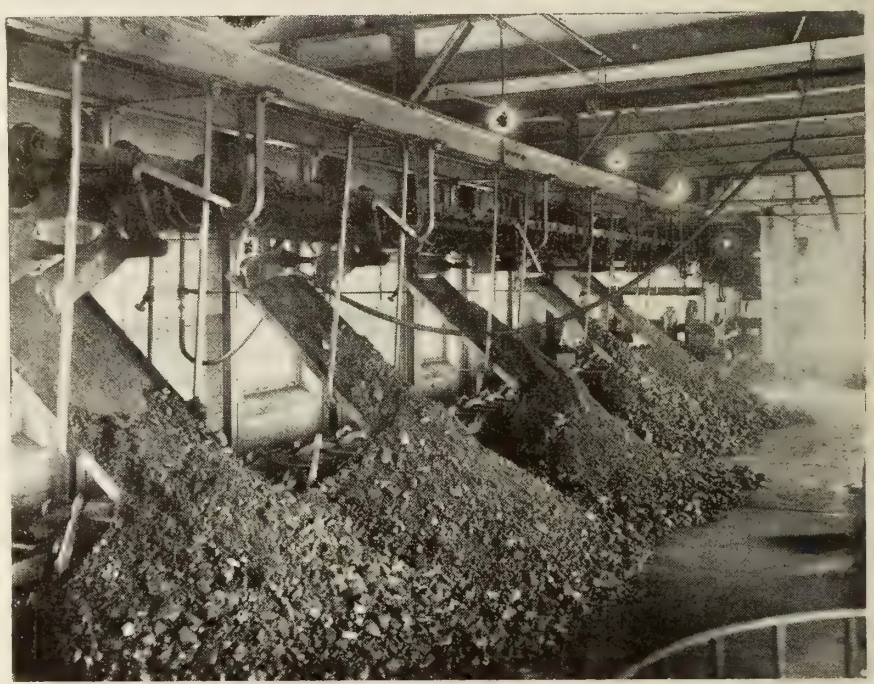
The coal used is American bituminous and, invariably, is shipped to the plant by rail and stored in piles, from where it is placed in carts and weighed on a Fairbanks scale, after which it is passed through a C. W. Hunt crusher and then elevated by means of a C. W. Hunt endless bucket conveyor to the top of the boiler house and dumped into the bunkers for supplying the old boiler house. A cross conveyor is used to deliver the coal to the new boiler house bunkers.

Owing to the heavy demands of the sugar refinery for large quantities of steam and water, it is imperative that no interference take place in the supply, and to insure constant service the system of water feed to the boilers has been installed on the interchangeable system, where front, back or cross connections, eliminate the possibility of temporary shut downs through the failure of some portion of the plant equipment.

For the oil service a 55,000 barrel steel storage tank has been erected some distance from the main building. This tank is provided with steam heating coils at the base and the oil is kept at approximately 60 degrees throughout the winter months. The condensation from this heating system does not return to the boilers, owing to the possible presence of oil in the water, and, therefore, is allowed to pass direct to the sewer.

Adjoining the large storage tank is the small pump house in which is installed a Connersville Lobe centrifugal pump, direct connected to a 7½ h.p. G. E. motor. This unit is located six feet below the base lever of the large storage tank, so that the oil flows to the pump house by gravity. From the pump house the oil is delivered through a 6 inch. pipe to the auxiliary tanks located in a small concrete building adjoining the new boiler house. The floor level of the auxiliary pump house is two feet above the bottom of the 8,000 gallon tanks, the ends of which extend into the pump house, with the greater portion outside the building but covered with three feet of earth. No woodwork, whatever, is used in this building and it is absolutely fireproof.

The conduit from the storage pump house to the auxiliary tanks is located 5½ feet below the ground surface, has a cross sectional area of 12 by 24 inches, and is made of wood, the total length being about 1,000 feet. Concrete manholes are provided every 200 feet. The 4 inch steam line is housed in this conduit and both it and the main delivery line for the oil are supported on rollers to take care of the expansion and the contraction. Heating of the oil storage can be done either with exhaust or live steam. The feed line is equipped with thermometers and safety valves.



COAL CARRIERS AND BUNKERS

Before passing into the three auxiliary tanks, each of which has a capacity of 8,000 gallons, the oil is metered by a Niagara meter. Each tank is fitted with indicators that show at a glance the height of the oil in the different tanks. Each tank is connected to a National Supply Co. rotary oil pump, direct connected to a 5 h.p. motor, one set delivering to the old boiler house, one to the new boiler house, and the other to the char kilns. As is the case in the feed water system, the oil piping layout is so arranged that the delivery is interchangeable, it being possible for any set to deliver oil to either of the other two departments.

Before the oil is delivered to the various burners it is passed through a National Supply Co. oil heater, which is steam heated on the contra-flow principle. From the main feed line the oil, at a temperature of 125 degrees Fah. goes to the burner where it is atomized by superheated steam.

For supplying light and power for the different departments and machines throughout the refinery, three large units are installed; one 600 h.p. Allis-Chalmers corliss engine direct connected to an Allis-Chalmers generator, one 400 h.p. Laurie corliss engine belt connected to two Allis-Chalmers generators; and one 100 h.p. Polson engine belt connected to an Allis-Chalmers generator. All engines are equipped with forced oil circulation.

PARTIAL VIEW OF ENGINE ROOM

Some Interesting Notes on Fuel Economy

The Following Article, Taken From a Report Made by C. E. Stroymeyer, is of Great Value to All Those Interested in Steam Plants

CERTAIN works, such as gas works, smelting works, forges, rolling mills, etc., consume far more fuel for heating purposes than for power. In these works much waste heat escapes up the chimneys of the heating furnaces, which might be saved by passing the waste gases through boilers. Very often this plan is carried out, but it is attended with inconveniences, even dangers, and each case must, therefore, be treated on its merits. Take, for instance, a heating furnace for armour plates. The value of a single plate may perhaps be equal to that of a boiler which might be installed over its furnace. The furnaceman has to watch the temperature and generally rivet his whole attention on the glowing armour plate. Suddenly the fireman tells him that the feed pumps will not work, so that the heating has to be interfered with and the plate perhaps spoilt. Then again the cranes and lifting arrangement around heating furnaces require much space, and it is not always an easy matter to find room for a boiler over or near a heating furnace. Another trouble is that such boilers, instead of being close together and under a central control and easily looked after, are scattered all over the works with isolated attendants, and, as is proved by the relatively frequent explosions of such boilers, they are not cared for as well as they ought to be.

Certain other works are practically pure power consumers; they use very little heat either for furnace work or for boiling and similar processes. These include engineering and hardware works, shipyards, sawmills and woodworking factories, rubber works, corn mills and seed crushers, water works, drainage works, collieries, power stations, electrolytic works and similar ones. Spinning mills, both for cotton and flax, also belong to this class, but they are often combined with weaving and other textile works, which use up the waste steam from the engines, and may form a single system as explained under the next class. It is obvious that if many of these works are grouped together in districts, as is for instance the case in the shipbuilding and certain engineering trades which have settled down on the Wear, Tyne, and Clyde, it may be advantageous to provide power from central stations if, as should be, it can there be produced economically.

In 1915 a brief report was prepared dealing with the coal consumptions of various types of steam engines under practical working conditions. It was then found that, on an average of about 30 cases, compound engines working at about 100 lbs. per square inch, consume about 2-7 lbs. of coal per i.h.p. net. Compound high-pressure engines consume about 1-85 lbs. of coal, and about 1-45 lbs. if superheated steam is used. The last-named consumption amounts to over 5½ tons per horse-power year continuous working, or 8,760 hours.

Most of the works dealt with were cotton spinning mills, which used up as much steam for heating and boiling purposes as would be produced by the burning of about 0-6 lbs of coal per i.h.p. per hour. This addition increased the above averages respectively to 3.3 lbs., 2-45 lbs., and 2-05 lbs. per i.h.p., except in a few cases where the totals were affected in a different way. In these latter works steam for heating, etc., is abstrated between the high and low-pressure systems of the engines. In the high-pressure system it has parted with the theoretical heat equivalent of the work done, and, as the drawn-off steam is required in the works for heating, this portion of the power has been produced at a minimum cost. Assume that a compound engine is developing 50 h.p. in the high-pressure cylinder, which is being supplied with 1,800 lbs. of steam per hour. Then assume that 400 lbs. of steam are withdrawn from the intermediate receiver. This leaves 1,400 lbs. for the low-pressure cylinder, which develops 30 h.p., making a total of 80 h.p. with a steam consumption of 1,800 lbs. This includes 400 lbs. of steam abstrated for heating purposes. A slightly smaller engine of exactly the same type would develop 80 h.p. with a steam consumption of 1,600 lbs. of steam, but the boiler would have to supply 400 additional pounds of steam for heating purposes, making a total of 2,000 lbs. as against 1,800 lbs.

Assuming that 1 lb. of coal evaporates 7½ lbs. of water, then in the above two cases we have in the first case a coal consumption of 3 lbs. of coal per i.h.p., including steam for heating purposes, and in the second case 2 2-3 lbs. for power, and 2-3 lbs. for heating, making a total of 3 1-3 lbs. or 11 per cent. more than in the first case.

The third class includes all those works in which more steam is used for heating and boiling purposes that can be supplied by the power-producing engines—and in many cases full advantage is taken of the fact that, when passing through an engine, steam only parts with the mechanical equivalent of heat for the power produced, as explained above, equal to say 2-5 lbs. of steam or 1-3 lb. of coal per i.h.p., and that all the exhaust steam can still be used for heating purposes. These works, therefore, obtain their power at the very cheapest possible rate, say 1¼ tons per horse-power-year continuous running, which under pre-war conditions of price is even cheaper than the often-quoted Scandinavian rates for electric power of 35s. per horse-power-year. Nevertheless it is these very economical works which have impressed some people as being extremely wasteful, and which have doubtless led to wild statements indulged in, even by a Cabinet Minister, about coal consumption being still as high as from 5 lbs. to 7 lbs. per i.h.p. Take the case of a dye works. It has two batteries of boilers, one high and one low pressure. Each printing machine is driven by its own little high-pressure engine; its own exhaust, supplemented sometimes by steam from low-pressure boilers, warms the drying cylinders. Doubtless each one of these engines consumes say 50 lbs. of steam per i.h.p., but it abstracts neither more nor less than 33,000 × 60 minutes, divided by 778 foot lbs. = 2,545 B.T.U., which are approximately equal to an evaporation of about 2½ lbs. of water and represented by the combustion in the boiler of 1-3 lb. of coal. The 50 lbs. of steam, less about 2-5 lbs. condensed in the engine, due to work done, pass into the back-pressure exhaust pipes, and are fully utilised for heating, boiling, and steaming purposes. The weight of fuel converted into power depends, not on the efficiency of the engine, but on that of the boiler. The weight of steam available for boiling purposes is practically a minimum if no condensation takes place in the engine, i.e., if the steam be superheated and the back pressure fairly high. Misled by the apparent wastefulness of using a number of small high-pressure steam engines throughout the works, occasional owners have been persuaded to replace them by electric motors. These changes have been absolute failures on a very large scale, tens of thousands of pounds having been spent with no other effect than that of increasing the coal bill enormously. The steam required for heating and boiling remained as high as ever, but the power instead of costing only 1-3 lb. of coal, as in the past, had now to be paid for by say 1-5 lbs. and even more.

A great saving of fuel could be effected if the above-mentioned well-established principle were to lead to the combination of works which require only power and such as use steam by heating. For instance, in the salt districts there used to be electrolytic works which used power, and close at hand were salt pans which required steam. The latter could have been worked free of cost with steam from the electrolytic works, or these could have had their power for ¼ lb. of coal per i.h.p., the salt pans paying for the steam used. This principle has to a certain extent been adopted at some power stations which sup-

plied exhaust steam to surrounding buildings for heating purposes. In the textile industries happy combinations of this sort are also not unknown; the spinning and weaving sheds which consume much power, supply steam to auxiliary sheds in which washing, printing, etc., is done, and where, consequently, all the exhaust steam is utilised.

The leading industries of this third class are bleaching, dyeing, calico-printing, weaving, most of the woollen industries, paper making, sugar refining, brewing, soap making, laundry work, and some chemical works.

In view of the increasing scarcity and dearness of coal, and the probability that some works may wish to reorganise their steam plant, it seems desirable to deal with steam and power utilisation in some detail, more particularly as manufacturers are likely to be confused in the near future by the central power stations which have been created by Act of Parliament, who will claim that their supply will prove to be a cheaper one than the production of power at the works. Their claim is based on the assertion that a central power station can use large power units and work more cheaply than the manufacturers who use small units. But this advantage, if it is a real one, must be very small, for it is claimed for moderate-sized dynamos that they work with an efficiency of 90 to 95 per cent., and therefore the possible gain by using very large ones can at best be only a small one. Another claim, which conflicts with the above is that central power stations can produce power with small units at the various collieries by using refuse coal for fuel. This is a doubtful claim, for it is based on the assumption that it will pay to mine the lowest and dirtiest layers of coal which are now, as a rule, left underground. Will it pay to bring it back to bank? If this dirty coal is to be mined and raised together with the good coal, it has to be picked which is an expensive operation; if it can be mined separately, perhaps by working two shifts at the good coal and one shift at the bad coal on the floor, the profit of the third shift would be a negative one. The labor would certainly be equally great, this impure coal being very hard, and its value could hardly exceed 30 per cent. of that on the good coal. Suppose the profit on the good coal to be 10 per cent. or the cost of getting it equal to 90 per cent. of its final value, then the cost of getting the dirty coal would be equally great, and as its value is, say, 30 per cent. of the good coal the loss would be 60 per cent., which is 200 per cent. on the value of the refuse.

Another claim advocated by central stations is that their load factor will be very small and with it their capital outlay. This comparison is valid only between central stations, but not between the works who would use their power. Those which run night and day have no peak load and are under even more favorable conditions than central power stations, who very naturally try to capture them so as to reduce their peak loads. Other works which run for, say, only eight hours a day have one unalterable peak load during these eight hurs, and their capital outlay on motors, etc., is proportioned to this peak load, which is 200 per cent. in excess of the average load. It does not affect their capital outlay whether the central station has or has not a heavy peak load, but it may affect the charge which the central station has to make for its supply.

All things being equal a factory ought certainly to be able to produce its power more cheaply than the price for which it could be supplied from outside, but there are, of course, cases where the absence of a good water supply, the saving of engine and boiler space, would make it profitable to obtain an outside supply.

In the following remarks it is proposed to deal only with power production at the individual works.

As far as can be ascertained electric losses are about equal to the belt and shaft losses in a well-planned factory, but unquestionably motors for driving are a great convenience, and the capital outlay involved in their adoption is very often justified, more particularly as their upkeep is small.

It is claimed for motors that they run at a very uniform speed, but this regularity depends entirely on the governing devices of the central engine, which in power stations are not always of the best. At any rate, as long as the central engine has a good governor it does not matter, as regards speed constancy, whether the power is transmitted electrically or by shafting. Irregularities no doubt occur if powerful machines are coupled to the ends of long driving shafts and are suddenly thrown in and out of work, but this is merely a bad arrangement and not an unavoidable evil. Even electric transmission would be similarly affected in a badly-designed factory.

A more important question, however, is that of steam economy, and whether reciprocating engines, turbines, or internal-combustion engines should be used; also whether it is better to use one large central engine or a number of small ones.

As regards internal combustion engines, it should be pointed out that theoretically, and to a certain extent practically, they are at present the most efficient power producers from fuel, and if it be intended to use up the waste heat from these engines there should be no insurmountable difficulty in passing their waste gases along pipes to those points where heat is required in the same way as steam is now carried through the work. It does not appear that this idea has been carried out, and it is certainly associated with the inconvenience that hot gases cannot be blown into water for boiling purposes, and, therefore, costly heating coils would have to be provided; but these hot waste gases might prove very efficient for drying purposes. They could be, and are, used for heating water in boilers and heaters.

As regards steam engines there can be little doubt that turbines will come largely into use, not only because their exhaust steam contains no grease, and can be used for almost any purpose without injuring the goods, but also because turbines are now so constructed that steam can be drawn from them at any convenient pressure and up to almost any amount.

Two extreme cases present themselves: Firstly, factories in which more steam is required for heating, etc., than can be passed through the engine; secondly, factories in which only a small portion of the steam passing through the engine is used for heating, etc.

It is already been explained that an engine whose waste steam is utilised is using only 2-5 lbs. of steam per horse-power hour, equivalent to one-third pound of coal. Such an engine is merely abstracting the power required on the spot, and passes on the surplus power or steam. It acts like a pulley belt on a main driving shaft of a factory. That shaft may be carrying a few hundred horse-power to the end of a large shed, and though this power passes through a number of pulleys, each one only abstracts the exact amount required locally. Therefore, as regards cost of power it does not matter whether a high back-pressure engine whose exhaust steam is used for heating is an efficient engine or not; it unalterably supplies power at a cost of, say, 2-5 lbs. of steam or one-third pound of coal.

In order to obviate the use of supplementary low-pressure mains, or where these are absent, the small engines which drive single machines which have to be heated by steam are made purposely inefficient, or rather they make themselves inefficient by a rise of the back pressure, so that consumptions of 80 lbs. or perhaps even 100 lbs. of steam per horse-power could be found in some works. Suppose now that a machine which is heated by the waste steam is improved so as to require less steam, then the inefficient engine will have to be replaced by a more efficient one, otherwise an enormous waste will result, due to blowing the exhaust steam into the air. As the steam demand is still further curtailed, the economy of the engine will have to be still further increased until a point is reached where the surplus steam must be dealt with efficiently by condensation.

This case is represented by cotton mills and similar works, and an occasional practice is to tap the engine for intermediate pressure steam. For convenience of studying the question we may imagine the driving shaft of such a factory to be coupled to two engines, the one of the most economic design, with superheaters and surface condensers, and the other one so designed that it exhausts into a low-pressure main. This one would be an inefficient engine for although it is converting only 2-5 lbs. of steam into power it is actually consuming anything up to 100 lbs. It will

however, be seen that the more efficient this wasteful engine can be made, the better.

Assume that the total power required is 800 i.h.p., and that the works also require 6,000 lbs. of steam per hour. Assume that the condensing engine, or the condensing part of the engine, consumes 15 lbs. per horse-power hour, and that the inefficient part consumes 62.5 lbs. per horse-power hour; then as the inefficient engine abstracts 2.5 lbs. for power, there remains 60 lbs. for heating per i.h.p., and therefore the inefficient engine must develop 100 h.p., while 700 h.p. are developed by the efficient engine. The steam consumption will be $700 \times 15 + 100 \times 62.5 = 16{,}750$ lbs. per hour. Subtracting the 4,000 lbs. for heating, the steam consumption is 13.44 lbs. per i.h.p. Assume now that the inefficient engine requires only 32.5 lbs. per horse-power hour, of which 2.5 are converted into power and 30 lbs. are passed away for heating purposes. Again, as 6,000 lbs. are required for this purpose, the inefficient engine must develop 200 h.p., leaving 600 h.p. to be developed by the efficient engine. The steam consumption will now be $600 \times 15 + 200 \times 32.5 = 15{,}500$ lbs. per hour. Subtracting the 6,000 lbs. for heating, the steam consumption is reduced to 11.87 lbs. per i.h.p.

Thus by drawing steam from the engine at a point down to which it has not been working economically—for instance, at a point where the pressure is still fairly high, a saving of 10 per cent. on the cost of power can be effected. If the steam is tapped at the lower pressure the saving would be .21 per cent.

Doubtless turbine designers could arrange matters, partly by increasing the boiler pressure and the superheat, so that the high-pressure part of the engine would work at a maximum efficiency, but in any case it will always be desirable to have the back pressure as low as possible, and that means that the distributing pipes of the exhaust should be of a reasonably large diameter.

Pipe System Lagging, &c.	A. Condensation per sq. ft.

In the foregoing remarks it has been taken for granted that it will be found more advantageous, even in bleaching and dyeing works, to produce the power in a central engine and distribute it either electrically or by shifting, than to have small steam engines attached to the various machines and to utilize their exhaust steam locally.

One of the considerations which led to this view was that as it is practically impossible to arrange that the weight of the exhaust steam shall always be exactly what is required for heating, and because most of these machines have to be heated up before their own little engine turns them, it is necessary to provide a system of low-pressure mains, in addition to the high-pressure mains, and then of course the loss by radiation must be greater than it would be with only one system of pipes. The other consideration is that even if there were no low-pressure distributing pipes, no serious radiation losses would result if the small high-pressure pipes were replaced by large low-pressure ones. As equal weights of steam are required, the sectional areas of low-pressure pipes would have to be made larger than the high-pressure ones in the inverse ratio of the two pressures. The diameters would, therefore, be in the inverse ratio of the square roots of the pressures, and the radiation would be in the same proportion if the temperature were the same; but the high-pressure steam has a higher temperature than the low-pressure steam, and also a greater density, which should increase the rate of heat transmission in proportion to the increased density. Mr. A. Fischer's experiments on this subject indicate no such effect in one comparison, and only a slight one in three others, and taking the average of his four comparisons the conclusion to be drawn is that the radiation losses instead of increasing with decreasing pressures are sensibly the same for high- and low-pressure pipes, provided that their diameters are made to the inverse ratios of the square roots of the respective absolute pressures. As an example, take a pipe which has to deliver 6,000 lbs. of steam per hour at a velocity of 50 ft. per second. In case A let the absolute pressure be 152 lbs., the corresponding temperature being 360 degs. Fah. and the volume of 1 lb. 3.04 cub. ft. In case B, the absolute pressure is 76 lbs., the temperature 307 degs. Fah., and the volume of 1 lb. is 5.76 cub. ft. The respective diameters of pipes will be 4.32 in. and 5.94 in., and the surfaces of 100 ft. of these pipes would be respectively 113 sq. ft. and 155 sq. ft. The estimated condensations are contained in Table I.

The average ratio shows a slightly increased condensation of 2 per cent. for the low pressure (B) pipes. This is of no practical importance, and when rearranging a factory the relative merits as regards radiation of high and low pressure exhaust steam need not be gone into, provided the low-pressure pipes are made larger than the high-pressure ones as explained above. The choice of diameter depends on the loss by radiation and on the loss in the engine due to back pressure.

The West Penn Power Co. of Pittsburgh, Pa., have applied for charters for building power distribution lines throughout Clarion County. The old 33-cycle current will be replaced by standard 60 cycle. Many mines and industrial companies are expected to take advantage of the new service and electric current.

HANDLING ASHES FROM TWENTY-TWO BOILERS BY CENTRIFUGAL PUMPS*

By using water to wash away ashes from twenty-two 500-h. p. Babcock & Wilcocks boilers in the Lake Linden (Mich.) power plant of the Calumet & Hecla Mining Company only two eight-hour shifts of two men are required. In this system the ashes are dropped from ash hoppers into a 30 in. (75 cm.) semi-circular steel trough, supported on a metal framework as shown in the accompanying photograph. The ash hoppers are large enough to hold the ashes from two cleanings of the boiler under any conditions, and if the coal is of a fair quality, the hoppers will hold three cleanings of ashes. The pipe leading into the trough is an 8 in. (21 cm.) water main, and after the valve in this main has been opened the ashes are gradually dropped into the trough and washed away to centrally located pumps. The troughs are arranged in the shape of a letter H with boilers along each side and with the dumping place for the ashes in the center. The ashes are washed on to a grating from each side and dropped down into duplicate centrifugal pumps each of which is of sufficient capacity to handle the ashes. Any large pieces of clinker are broken up when they get on to the straining bars.

The storage capacity of the ash hoppers permits the use of only two shifts of ash handlers, each working eight hours. Two men work from 7 a. m. to 4 p. m., and two others work from 7 p. m. to 4 a. m., with one hour off each shift for meals. This leaves a three-hour stretch between each shift and two meal hours when there are no ash handlers on duty. In this way it requires only thirty-two man-hours to handle about 50 tons of ashes, which is at the rate of more than 1.5 tons of ashes per man-hour. This proved a very convenient and economical method of handling the ashes in the power house, but the principal gain over the old ash-car system is in the elimination of the cost and inconvenience of attempting to remove the ashes in cars.

The pumps each have a maximum capacity of 1,800 gal. per minute (110 l. per second) against a hydraulic head of 30 ft. (9 m.). Each pump is driven at 510 r.p.m. by the belt from a 50-hp., 440-volt., three-phase, 25-cycle, 750-r.p.m. squirrel-cage induction motor. The pump impellers were specially designed of hard cast iron to withstand the action of the ashes. It has been found that the impellers have to be renewed about every seventh week, and the cost of every such change is about $30. The pumps are so connected that they may be operated independently or together, as desired.

A Paper on Modern Boiler Practice

The Following Paper Read Before the Engineering Institute of Canada Gives a Very Complete Account of the Trend in Modern Boiler Design and the Economies Effected Thereby

By F. A. COMBE, A.M.E.I.C., Consulting Engineer

(Continued from last issue.)

Modern Boiler Design

In modern direct fired boiler design, the principle of higher gas velocities is also adopted where advantage can be gained, and the tendency is to reduce the heating surface, or increase the evaporative rate, of the boiler proper employing it primarily for steam raising, and adding additional independent surface for water heating, in order to get a more efficient total heat transfer by the increase in temperature difference for a portion of the total heating surface. This practically means combining a boiler and economizer in one unit proportioned to give the highest efficiency and resulting in less total heating surface and considerable saving in space and of many of the losses incident to the use of separate economizers.

A cross section of such a boiler is given in Fig. 5, a study of which will show that the maximum effect of direct radiation is obtained while the hot gases, entering the tube bank at the uptake end and passing at right angles across the staggered rows of tubes at high velocity through the long passages of the boilers and economizer fulfil conditions conducive to high efficiency.

In Figs. 6 and 7 are given two views of one of four boilers of this type recently installed at the Montreal Tramway Company's plant at Hochelaga, being the largest boilers in Canada. Each of these boilers contains 5,625 square feet heating surface in the boiler proper or steam raising section and 2,909 square feet economizer or water heating section, giving a total heating surface for the unit of 8,534. These boilers are capable of easily generating over 40,000 lbs. steam per hour at 200 lbs. per square inch steam pressure and 150 deg. F. superheat from a feed water temperature of 120 deg. F. It will be seen that the equivalent evaporative rate for the boiler proper is as high as 8.75 lbs. per square foot heating surface, or 5.75 lbs. for the whole unit, in spite of which, it is possible to reduce the temperature of the gases below what it would be with a standard boiler of 3.5 lbs. normal evaporative rate, that is to say, with considerably more heating surface. Each unit is steel cased, lined with special non-conducting material to minimize air leakage and radiation, and fitted with double chain grate stokers, having a total grate area of 224 square feet.

An interesting feature in connection with these units is the draft apparatus comprising a specially formed stack for each pair of boilers, having a constricted throat into which a high pressure air blast is delivered through a nozzle from a small fan; the action being that of an ejector, inducing a suction in the flue connections to the boilers.

A complete test of these boilers has not been made, but in a paper read before the British Institute of Civil Engineers about a year ago, details are given of a test made on a boiler of this type, approximately the same capacity, but containing 4,963 sq. ft. boiler heating surface and 4,086 sq. ft. economizer surface, in which a thermal efficiency of 88.33 per cent. for the unit was obtained, the exit gas temperature being 293 deg. F., and the evaporation per sq. ft. boiler heating surface 9.53; while another test made in 1916 at the Hague municipal plant with a slightly smaller unit gave an overall efficiency of 88.41 per cent. It is probably not possible to obtain such efficiencies with the coals usually obtainable here, but it indicates that a very high efficiency in steam generating equipment has been reached.

Boiler Efficiency

It is to be understood that in a boiler of the usual construction, where the temperature of the water in the boiler is practically at the temperature of the steam, it is obviously impossible to reduce the temperature of gases below that of saturated steam at the pressure carried, in fact, while it is possible to add heating surface to reduce the gas tem-

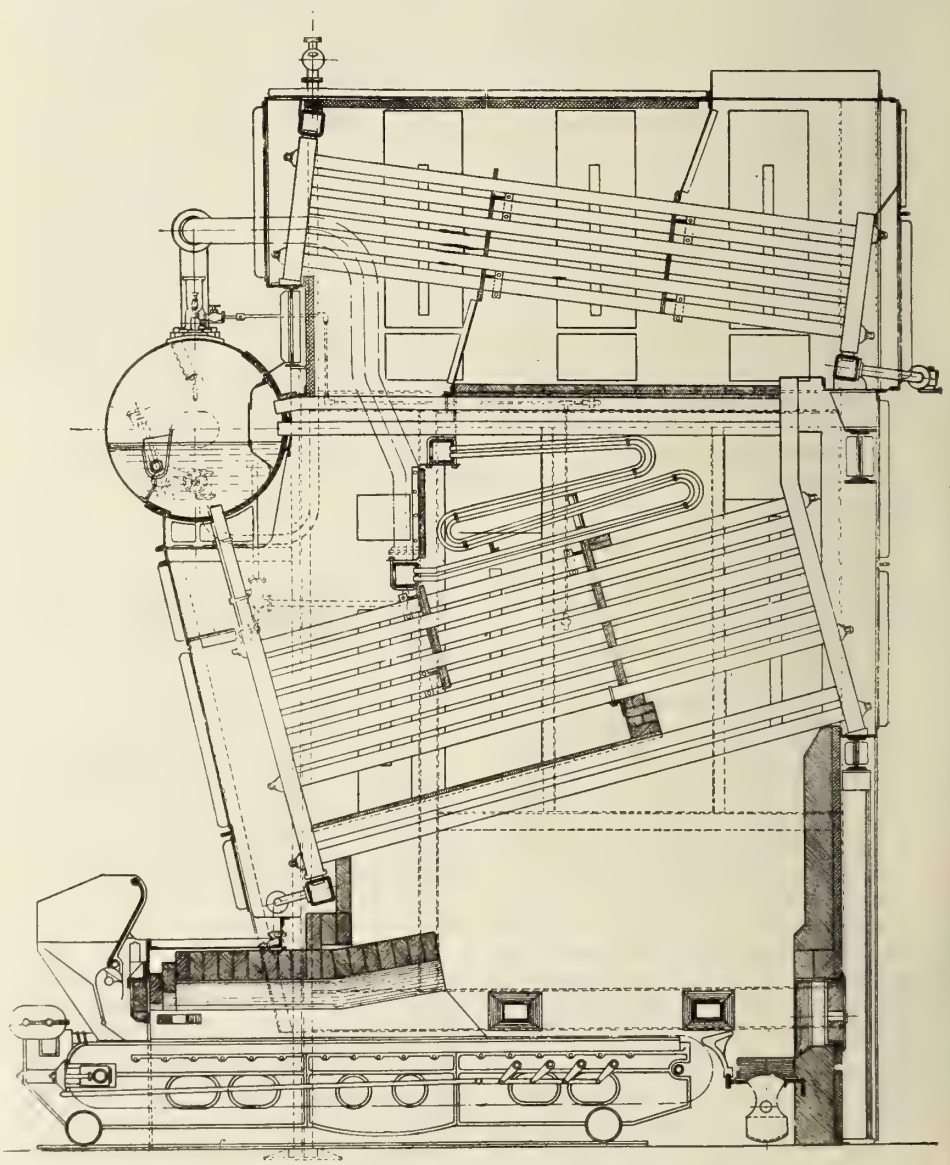

FIG. 5.

perature below 100 deg. above the steam, the very low transfer rate resulting from such a small temperature difference in the last passes of the boiler does not warrant the expense of the additional heating surface.

In a great number of published boiler tests the exit gas temperature is given as near the temperature of the steam, but such temperatures will usually be found to have been incorrectly measured, owing either to air leakage around the boiler damper or to radiation, as pointed out earlier in the paper. The saturated steam temperature referred to in this connection must not be confused with the superheated steam temperature leaving the boiler when a superheater is installed, as the exit gas temperature is often considerably below the superheated steam temperature, the superheater coils being placed in the high temperature gas zone.

For a proper consideration of the efficiency of a boiler, the steam pressure carried must be taken into account. It is not fair to compare the efficiency of a boiler operating at, say 100 lbs. pressure with a boiler operating at 200 lbs. pressure where the temperature of the boiler heating surfaces differs by 50 deg. and the necessarily increased flue gas temperature results in a greater heat loss with a coresponding reduction in the efficiency as usually measured. For this reason it has been proposed that the efficiency of a boiler be measured in terms of its "true" efficiency, or the ratio of the heat actually absorbed to the heat theoretically available for absorption, which latter value corresponds to a reduction of the temperature of the flue gas to the temperature of the steam. In the same way allowance is made in England and Europe for the burning of the hydrogen in the coal which leaves a boiler in the form of superheated steam, but which in a calorimetric analysis of the coal is condensed and its latent heat added in the heat value obtained. The revised heat value, corrected for the hydrogen content is termed the lower or nett calorific value of the fuel.

Stokers and Fuels

The greatest factor in the overall efficiency of a boiler unit lies, of course, in the combustion of fuel in the furnace. It is not within the scope of this paper to deal with the theory of combustion, and a great amount of literature has already been published on the subject, but one of the chief causes for inefficient combustion lies in the faulty design of the furnace and the lack of volume provided for the proper mixing and burning of the gases before striking the cool boiler heating surface. With hand firing under small boilers, the skill of the fireman in keeping an even, regular fire is also a big factor, but with larger boilers and automatic stokers a great deal of this work is taken care of, and, if operated intelligently, with the aid of recording instruments, a high degree of efficiency can be maintained.

The advantage of automatic stokers for plants of over 500 boiler horsepower has now become generally recognized and the only question for the engineer to decide is what stoker to instal. No type is suitable for all coals and conditions of service. Where boilers of a nominal evaporative rate of 3½ lbs. are to be forced to high capacities or where anthracite coal is to be burned, forced draft stokers will probably have to be used and in considering high overloads, allowance should be made for the extra upkeep cost generally entailed and the consequent need for reserve boilers.

Difficulties have frequently occurred through the installation of a chimney of insufficient height to freely take away the products of combustion from the furnace of a forced draft stoker when operating at a high rate, the assumption having been made that as there was an air pressure under the grate, very little chimney draft was necessary. The result has been that a pressure has built up in the furnace, causing excessive burning up of the brick walls by reason of the hot gases being forced into the cracks. A definite suction, say 1-10 inch of water, should always be maintained in a furnace of this type and as with boilers forced considerably above their rating the resistance through the boiler itself becomes considerable, it does not allow of much reduction in the height of chimney to be provided.

For steady running on continuous moderate loads, the natural draft stoker will probably give the best satisfaction; of this type the chain grate is the most common and probably the most logical way of burning high volatile coals, possessing the advantage of simplicity and ease of adjustment to suit the particular grade of coal and load conditions.

In view of the attention now being paid to the utilization of the Western Canadian lignites, it may be of interest to mention that a chain grate stoker was installed in 1913 in the University of Alberta, having a special setting of arches similar to that used in England and Europe and very excellent results have been obtained with the Edmonton lignites on this stoker, so much so, in fact, that several engineers in the Western cities have modified their standard stoker settings as far as possible to conform to it. A similarly set stoker has recently been installed at Moose Jaw, where the higher moisture Saskatchewan lignites will be burned, and from information received it promises to also prove satisfactory.

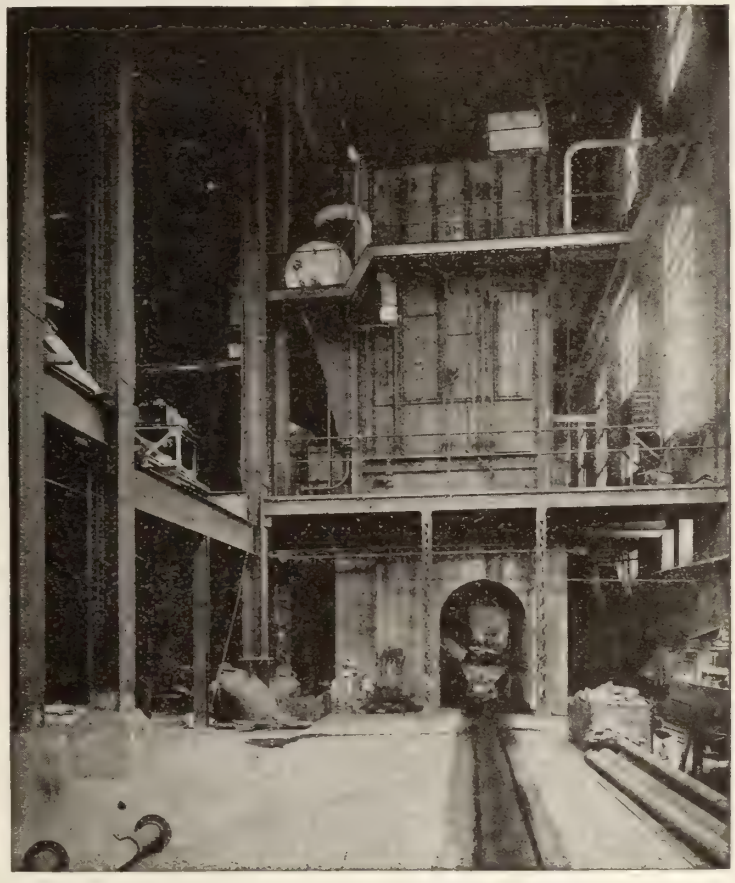

FIG. 6.

Fig. 8 shows the typical setting; the essential feature being the centre and back arch construction, which, by deflecting the gases and reflecting the radiated heat towards the front of the grate, drives off the moisture from the freshly fed coal. A front coking arch of the standard form is of no use for this class of fuel, as the excessive moisture prevents it getting hot and so hinders the ignition. This arrangement of arches is hardly suitable for burning higher grade bituminous coal, as the centre arch

would generally not stand up for long against the higher furnace temperatures, but it has been used extensively for low volatile or semi-anthracite coals, which cannot be burned satisfactorily with a natural draft chain grate stoker with the standard arch construction.

Oil and natural gas make excellent fuels in that high combustion efficiency and regulation can be easily attained with low operating cost and with increased cleanliness in the boiler room, but in Canada, oil is generally only economically available on the west coast, while natural gas is confined to but few localities, and the supply limited.

Powdered coal has been receiving considerable attention in recent years. At present the plant required for, and the cost of crushing, pulverizing and drying has generally limited its use to industrial plants where the fuel can be used in heating furnaces in addition to the boilers. For satisfactory operation, the coal must be pulverized to a degree equivalent to 95 per cent. through a 100 mesh sieve and should be dried to contain not more than 1 per cent. moisture.

A form of extension furnace is commonly used when fired under a boiler, the coal dust being fed through one or more nozzles into the furnace in a fine cloud. Air for combustion is partly carried in with the fuel and partly supplied through annular spaces around the nozzles, either under pressure or simply drawn in by suction. When properly regulated a high efficiency can be obtained and coal utilized which would be difficult to burn in the ordinary way, but care must be taken to avoid unconsumed coal being carried over into the boiler and also in handling the ash which settles in a molten slag condition to the bottom of the furnace, by reason of the high temperature attained, and which, if allowed to solidify, is very difficult to remove. As the finely powdered coal is in a highly combustible state, proper precautions must also be taken in the storing, distribution and firing to prevent explosions. Brickwork trouble from the high furnace temperature has been one of the difficulties to overcome with the burning of this fuel.

Blast furnace gas and by-product coke oven gas can be used to great advantage under boilers, a considerable advance having been made during the last few years in the efficiency obtained. This has chiefly been brought about through improvements in furnace design and types of burners, while the application of boilers of a similar design to those used for waste heat work now promises a still greater advance in this field.

Selection of Boilers

The best type of boiler to use in any plant must depend upon the conditions of service. For continuous steady loads such as in manufacturing plants where generally the boiler room does not receive special attention for operation, the standard boiler of 3½ lbs. evaporation per square foot heating surface will usually be found to be the best, with an installation of the regular separate cast iron economizer where conditions show that a saving will be made, and this is usually an easy matter to determine. An automatic stoker should also be chosen with a view to continuous steady service with the minimum cost for upkeep and repairs to stoker and furnace brickwork, and suitable for the particular class of coal which it is intended to burn.

In many manufacturing plants some kind of refuse can be utilized as fuel which usually requires a special form of furnace. Probably saw mills and pulp mills are the chief plants in this country where refuse is burned, being then in the form of hogged bark and edgings; and a straight extension furnace of the Dutch oven type is generally found to be the best, with a large surface of hot brickwork to drive off the moisture, when, as is usually the case, the wood is wet. Step grate furnaces are largely used in Europe. To obtain the best results, the areas and proportions of the furnace must be carefully designed; very often the chief consideration appears to be merely to get rid of the refuse without any effort to obtain the maximum efficiency, with the result that a considerable amount of coal is burned as an auxiliary which would not be necessary if the waste were properly utilized.

For large central stations and public service power plants, where floor space is of more value and load conditions special, the selection of boilers and stokers requires more study. In this service the load is usually very variable with short heavy peaks and a more elaborate layout and system of operation is justified. The general practice for these plants in the United States has been to get more and more out of the standard boilers of 10 sq. ft. per horsepower normal rating, in conjunction with regular economizers, by forcing them considerably during peaks. Particular attention is paid to good boiler and furnace design, and although the efficiency falls off at the high rates of driving, and the upkeep cost of brickwork and stoker is considerable, owing to the high furnace temperature, the practice has been considered warranted by the advantages gained. In these plants special precautions are taken to supply pure feed water, while expert attention is necessary for successful operation. In England and Europe the practice tends towards the use of boilers of the tvpe shown in Fig. 5.

The proper size of boilers to instal is, of course, governed by the size of the plant and the load conditions and no fixed rules can be laid down. In the United States there are some very large units, considerably larger than any installed in other countries, the Stirling boilers at the Detroit Edison Company's plant, shown in Fig. 2 having a normal rating of 2,365 boiler horsepower based on 10 square feet of heating surface per horsepower. In Canadian plants it will probably be a considerable time before units larger than 1,000 or 1,200 horsepower are warranted. There is a disadvantage in putting "too many eggs in one basket," as the failure of a tube or other cause of shut down means cutting off a big source of power and wasting a lot of coal, but in operation the efficiency is increased through a reduction of radiation and other losses over several smaller units.

Operation

There are comparatively few plants in Canada where a separate water purifying apparatus is installed; for small plants where moderate loads are carried on the boilers, some form of compound can be fed in with the feed water suitable for the nature of the water used, but as pointed out earlier, the boiler is not the proper place to treat the water and where the highest efficiency is desired or where boilers are to be run at high rates of evaporation, it is essential that the water be treated in a separate apparatus. In the most modern stations, the tendency seems to be towards the use of evaporators to purify the make-up feed water to ensure the absolute removal of all impurities, as in marine practice. It is not sufficient that heavy scale be prevented from actually adhering to the metal of the heating surface, as floating scale, which may temporarily lodge in one place, is apt to cause burning under high rates of evaporation. Oil is one of the most prolific causes for trouble in a boiler, the least sign of it often causing blisters on the boiler heating surface exposed to the furnace heat, even under moderate loads.

A trouble which may arise, unless proper precautions are taken, especially when using as feed water, the condensed steam from a surface condenser, is corrosion in the boiler and economizer from the air entrained in the water. The latest investigations indicate that it is the CO_2, and not the oxygen, present in the air which is the active agent in the corrosion and it is necessary that this be got rid of before feeding the water to the boilers, either by heating and the provision of efficient air escape pipes, or by chemical treatment with calcium hydrate (slaked lime). The use of air pumps which draw off the water and vapor together from surface condensers are particularly undesirable when the condensate is to be used for boiler feed as this water is strongly impregnated with air.

For efficiency and capacity it is also necessary that the outside of the tube heating surface be kept free from soot, and mechanical soot blowers are now being used to a great extent as an easy means of ensuring more regular and effective cleaning than is generally possible with the somewhat arduous task of hand cleaning with a steam lance.

While it is of first importance that good boilers and furnaces be installed, their value is to a great extent lost unless the boilers are kept clean and the plant efficiently run, and it is impossible to expect intelligent operation unless instruments and meters are provided as a guide for the operator. The old idea of

the fireman telling by a look at the furnace if coal was being completely burned is obsolete, and, after all, the furnace is only one factor of efficient operation, although the greatest. Some modern boiler rooms are now fitted with regular control boards and instruments by which losses can be immediately detected and located and there is no doubt that the cost of such indicators and the extra supervision entailed is saved many times over in the yearly fuel consumption. Coal scales and water meters are necessary for purposes of record and check on deliveries, yet they do not by themselves ensure efficiency in operation. If thermometers, draft gauges, flue-gas analysers, etc., are used intelligently as a guide for operation, the coal consumption will take care of itself; and with a proper log system, continuous records can be made over extended periods under actual operating conditions which are of real practical value and not subject to the often misleading conclusions resulting from short tests.

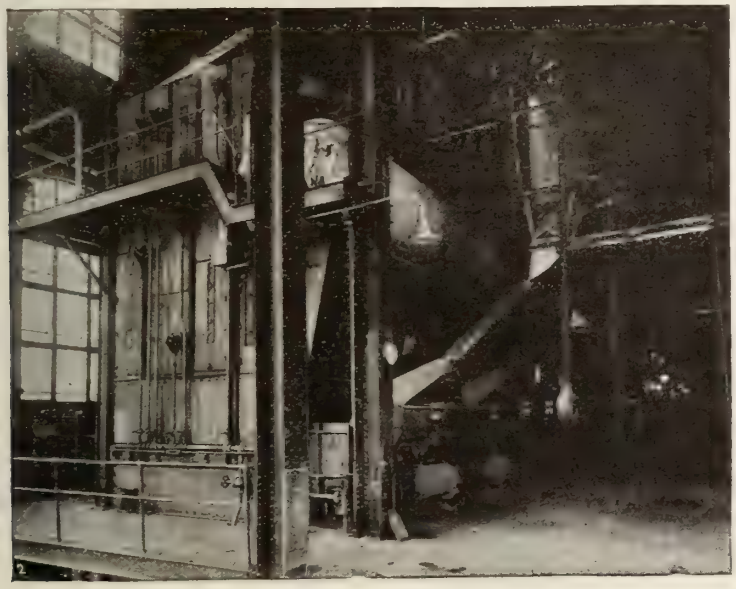

FIG. 7.

Probable Future Development

It does not seem likely that there will be any great departure in the near future from the present general design of boilers, but the probable adoption of steam at a higher pressure and temperature in turbines will lead to a certain modification with poossibly a more pronounced segregation of the evaporating and water heating surfaces. Several boilers of the type shown in Fig. 5 are already in service in England, and the United States, under a working steam pressure of 350 lbs. per square inch and a steam temperature of 700 to 750 deg. F., and others are under experimentation up to pressures of 500 and 600 lbs. These higher pressures, of course, prohibit the use of any flat stayed surfaces in boiler construction, and the very best material and workmanship must be employed; but from a constructional and operating point of view, higher pressures and temperatures will not be governed by boiler limitations.

With regard to methods of construction, welding of joints in drums does not at present seem likely to replace riveting, although it is receiving some attention and is used in conjunction with riveting on some marine boiler work.

During the last few years, several of the Canadian provinces have put into force very complete regulations to ensure safety in boiler construction and operation and an effort is being made for the adoption of a uniform code of laws for the whole Dominion. The advantage of this, in the protection it would afford to steam users, and the possibility of standardization for manufacturers would be very great; while if, in addition, a system of control, propaganda and educational work could be carried out by a fuel administration department, it would be of inestimable value to power plant operators and lead to conservation of our fuel resources which form a very large part in the cost of power production.

Next Exhibition will be held at Woodstock, June 22-24, 1920.

STEAM USED BY JETS

A recent article in "Engineering" gave some interesting results of investigations made into the amount of steam used by jets. The average figure is very much above what is usually estimated as the consumption of apparatus for increasing draught. The tests were made with nineteen varieties of boiler-firing apparatus in which steam jets are used, and the highest consumption noted was 21.4 per cent. of the steam produced. The lowest was 0.5 per cent., and the average 6.6 per cent. These figures should furnish some food for interesting thought.

Oil-Burning Furnaces is the title of a very interesting catalogue just received from the Gilbert & Barker Mfg. Co., of Springfield, Mass. There is an abundance of illustrations, showing clearly the details of the company's burners and furnace equipment, and there is some reading matter that sums up the value of this class of equipment in an especially clear and concise manner.

A Course of Instruction for the Graded Certificate

We Will in This Course Go Through the Mathematical and Theoretical Work to Cover Every Grade of Certificate Issued by the Ontario Board

By T. H. FENNER

THERE have been so many letters coming into this office with requests for instruction in the work for the graded certificate examination, that the need for a course has been strongly felt. In contemplating the work necessary, it has been realized that for some of those who want the more advanced grade, there will of necessity be a going over of old ground. However, the great majority of our correspondents wish to start from the beginning, and perhaps it will do no harm for some of the others to brush up their elementary knowledge.

The first thing taken up will be mathematics, and it will be assumed that every one can do the fundamental operations of addition, subtraction, multiplication and division. The course will, therefore, take up primarily vulgar fractions, go on to decimals, involution, evolution and the necessary mensuration which will be required. Having covered that groundwork, we will apply the knowledge gained to actual engineering problems, covering the boiler, steam engine, refrigerating and air compressor. The electric end will probably be dealt with separately and concurrently.

As this course is being undertaken for the benefit of our readers who will be candidates, it is hoped that if any points arise from time to time which are not perfectly clear, that they will not hesitate to write and ask for a fuller explanation. It is difficult sometimes to make a particular meaning clear to all, and the writer realizes this, having spent probably as much time as most in trying to see through an obscure point which was perfectly clear to others. On the other hand, there is nothing in the proposed examinations which should hold any terrors for the average man, and the bogey of formulae, and high technique, which is freely paraded, will be found to be a very harmless animal when approached boldly. Any man who has the initiative and confidence in himself to understand the handling of a power plant, has got the necessary intelligence to master the technical end of his work, if he applies himself to it. The obscure points will become clear, the seemingly hopeless will become simple, and the whole thing become of absorbing interest. The preliminary work is dry, we must admit. However, to be dry is the fashion now, and we will try and make it not too bad. Now that the preliminaries are over, let's go.

Vulgar Fractions

Vulgar fractions, or common fractions, are so called to distinguish them from the decimal fraction. The operations performed with them are those of addition, subtraction, multiplication and division, involution and evolution. A complete knowledge of the various steps required to perform these operations is absolutely necessary in the carrying out of calculations connected with the steam engine and boiler. While generally more complicated than the decimal, there are cases where their use is more convenient than the use of the decimal, owing to the ability to cancel, and thus simplify the work.

A fraction consists of two numbers, with a vinculum or dividing line between, the number on the top of the line, on the left hand side of the line if it is vertical, being known as the numerator, and the lower or right hand side number being called the denominator. The numerator expresses the quantity of parts, and the denominator the number of parts in a whole number. For instance, ½ or ½ expresses the fact that a whole number is divided into two parts and the fraction is one of the two parts. 13/64 similarly expresses that a number is divided into 64 parts, of which we are considering 13. The numerator subtracted from the denominator expresses the number of parts remaining, or in other words, the number that must be added to the numerator to make one unit. Thus 64 — 13 = 51 so that 13 + 51 = 64 and 64 1/64 parts makes one whole number. (An article by the writer which appeared in the December 20 issue of POWER HOUSE, entitled: "An Explanation of the Construction of Formulae," will be of use to the student at this stage.)

Fractions may be proper, improper, simple or compound. A fraction which is less than a whole number, such as ¾, ⅞, or 15-16 is a proper fraction. A fraction which is more than a whole number such as 16-15, 4-3, 3-2, etc., is an improper fraction.

A simple fraction is one that involves merely a numerator and denominator, such as we have seen, while a compound fraction includes several operations, such as:

$$\frac{\frac{3}{4}}{\frac{7}{8}} \quad \text{or} \quad \frac{\frac{1}{2}\left(\frac{7}{8}+\frac{1}{3}\right)}{\frac{3}{4}\left(\frac{9}{16}+\frac{7}{8}\right)} \div \frac{15}{16}$$

We will not consider these complications right away, but will explain the simpler operations first.

Supposing we wish to add together a number of fractions, say:

$$\frac{3}{4}+\frac{7}{8}+\frac{15}{16}+\frac{9}{32}$$

Before we can do so we must first find a common denominator. That is, we must find a way of expressing each fraction in the same terms, either 4ths, 8ths, 16ths, or 32nds, whichever is the most convenient. We proceed in this manner.

Take all the denominators thus:

4., 8., 16., 32

Divide the first one into each of the others:

$$4 \,|\, 8.\ 16.\ 32$$
$$2.\ 4.\ 8$$

Take the first figure of the quotient 2 and divide it into the remaining figures of the quotient:

$$4 \,|\, 8.\ 16.\ 32$$
$$2 \,|\, 4.\ 8$$
$$2\ \ 4$$

Repeat this operation with the remaining two figures:

$$4 \,|\, 8\ \ 16.\ 32$$
$$2 \,|\, 4.\ 8$$
$$2 \,|\, 4$$
$$2$$

Now multiply together all the divisors and the remaining quotient that is:

$$4 \times 2 \times 2 \times 2 = 32$$

and 32 is the new denominator. We now have to express each term in terms of the new denominator.

We have $\frac{3}{4} + \frac{7}{8} + \frac{15}{16} + \frac{9}{32}$. To get each term in terms of the new denominator we must divide each denominator into the new one, and multiply the numerator by the result. Take the first term. The denominator is 4. The new denominator is 32. 32 divided by 4 gives 8, and multiplying the numerator by 8 gives 24, which is the numerator of the first term with 32 as denominator. The

work is $\frac{32}{4} = 8, 8 \times 3 = 24$. The new fraction is $\frac{24}{32}$. The next term gives $\frac{32}{8} = 4$ and $4 \times 7 = 28$. $\frac{28}{32}$ and so on. The complete sum is $\frac{24}{32} + \frac{28}{32} + \frac{30}{32} + \frac{9}{32}$.

For convenience the sum is set down thus: $\frac{24 + 28 + 30 + 9}{32}$

Adding the numerators together gives 91 and placing this over the denominator gives the result of the sum as $\frac{91}{32}$ which is an improper fraction. To make this into a whole number and a fraction, divide 32 into 91: which is two and twenty-seven remaining, or $2\frac{27}{32}$.

This is a simple case and any one familiar with fractions would have found the new denominator, or to give it its proper name, the least common denominator, by inspection. The least common denominator is the least number which all the denominators can be divided into without a remainder. Let us take a mere difficult case add together: $\frac{3}{42}, \frac{8}{54}, \frac{9}{20}, \frac{3}{7}$

Take the denominators, and see if any of them will divide into any of the others: 42, 54, 20, 7. We see at once that 7 will divide into 42.

We see again will go into 54 and we get:

7 | 42. 54. 20
6. | 54. 20
9. 20

No further division is possible, so we have:

$$7 \times 6 \times 9 \times 20 = 7560$$

Now, instead of setting it down as above, we might do it a simpler way. Thus: 42, 54. 20, 7. We see 7 goes into 42. Cross out 42 and put the figure 6 underneath. 6 goes into 54. Cross out 54 and put 9 underneath. The result looks as follows: 6, 9, 20, 7

Multiply the figures remaining and get the new denominator 7560.

The new fraction will be

$$\frac{540 + 1120 + 3402 + 3240}{7560} = \frac{8482}{7560} = 1\frac{922}{7560}$$

It soon becomes easy to determine a denominator at almost the first glance if the fractions are ordinary ones as in our first instance. For instance, any fraction dealing with the ordinary divisions of an inch on a rule are always added mentally, even though some men will express a measurement as five-eighths, a sixteenth, and a thirty-second. $\frac{23}{32}$ instead of $\frac{23}{32}$.

Subtraction of fractions is performed in exactly the same way as addition as far as getting a common denominator is concerned. If we wish to subtract $\frac{3}{4}$ from $\frac{15}{16}$ we see at once that the L. C. D. (least common denominator) is 16 and the problem is $\frac{15-12}{16} = \frac{3}{16}$.

Suppose we have $\frac{13}{16} - \frac{3}{20}$. Sixteen will not go into 20 but perhaps there is some other number that will go into both 16 and 20; 2 will go into each, so will 4. Then we have $\frac{4 \mid 16 \quad 20}{4 \quad 5}$, and multiplying $4 \times 4 \times 5 = 80$ we get a new denominator. The problem becomes

$$\frac{13}{16} - \frac{3}{20} = \frac{65 - 12}{80} = \frac{53}{80}$$

In any case of addition or subtraction of fractions, if the various denominators will not divide into each other it is sometimes possible to find another number which will go into all of them, in which case the new number and the various quotients will be the new denominator. Take $\frac{7}{15}, \frac{8}{21}, \frac{9}{12}$, none of these will divide into each other, but each is divisible by 3, and we get

3 | 15, 21, 12
5, 7, 4

Then $3 \times 5 \times 7 \times 4 = 420$ which gives $\frac{196}{420} \quad \frac{160}{420} \quad \frac{315}{420}$

Take another case again more difficult at first glance. Find the L. C. D. of $\frac{7}{8}, \frac{9}{20}, \frac{18}{42}, \frac{16}{34}, \frac{8}{50}$. None of these will divide into each other. However, inspection shows us that 4 will divide into the first two terms. We proceed as follows:

Divide the first line by 4. The terms that cannot be divided are set down again in the second line. Looking at

4 | 8. 20. 42. 34. 50
5 | 2. 5. 42. 34. 50
2 | 2. 1. 42. 34. 10.
1. 1. 21. 34. 5.

the second line we see 5 will divide into 5 and 50, so we proceed, setting down again the terms not divisible by 5. We see 2 will divide into 2, 42 and 10, and we go ahead again, setting down terms that cannot be divided. We have left 21, 34, and 5. No single number will divide any two of these. We might divide 21 by 3, but it would make no difference as we would have still two terms left. We therefore proceed with the multiplication of the quotient and divisors, and get

$$4 \times 5 \times 2 \times 21 \times 34 \times 5 = 142800.$$

This is a big number, but nothing like as big as if we had not reduced it down by gradual cancellation. In that case we would have had $8 \times 20 \times 42 \times 4 \times 50 = 11.424,000$, which is much more unwieldy.

Now let us take a case where we have both addition and subtraction.

What is the sum of

$$\frac{7}{8} + \frac{9}{16} + \frac{3}{4} - \frac{1}{2} - \frac{3}{16} - \frac{1}{4}$$

The first step is to get the L. C. D. We see at once that it is 16. Then our sum becomes:

$$\frac{14 + 9 + 12 - 8 - 3 - 4}{16}$$

Now, in solving an expression like this we take all the terms with a plus sign and add them together, and all the terms with a minus sign, and add them together. Then the sum of the terms with minus signs is subtracted from the sum of the terms with plus signs. When a term has no sign before it the plus sign is always understood. We have then $14 - 9 - 12 = 35$, and $(-8) + (-3) + (-4) = -15$. Then our statement is

$$\frac{35 - 15}{16} = \frac{20}{16} = 1\frac{1}{4}$$

Let us take another case for example: What is the sum of

$$\frac{8}{12} - \frac{7}{8} + \frac{9}{32} - \frac{7}{42} - \frac{3}{4} - \frac{15}{16} - \frac{1}{64}$$

Our least common denominator will be

16 | 12. 8. 32. 42. 4. 16. 64.
4 | 12. 8. 2. 42. 4. 1. 4.
3 | 3. 2. 2. 42. 1. 1. 1.
2 | 1. 2. 2. 14. 1. 1. 1.
1. 1. 1. 7. 1. 1. 1.

L. C. D. $= 16 \times 4 \times 3 \times 2 \times 7 = 2{,}688$.
The sum will be:

$$\frac{1792-2527+756+448-2013-2520+42}{2688}$$

Add together

1792, 756, 448, 42 = 3038
2527, 2013, 2520 = 7060
3038—7060

We have therefore $\frac{3038-7060}{2688}$. The quantity after the minus sign is the greater so the answer will be a negative quantity.

We get $-7060+3038=4022$, and the result of the sum is

$$-\frac{4022}{2688}=-1\frac{1334}{2688}.$$

Cancellation

Before attempting any operation on fractional numbers, it is always best to reduce them to the lowest possible terms and thus simplify the work. Supposing you have a term like $\frac{28}{32}$. If the top and bottom terms, or the numerator and denominator can each be divided without remainder by the same number the resulting fraction will be exactly the same in quantity but much easier to handle. Looking at the fraction $\frac{28}{32}$ we see at once that both terms can be divided by four, which gives $\frac{7}{8}$ as the result, which is much easier to grasp than $\frac{28}{32}$. The same process can be applied to any fraction and the ease with which it can be done is a matter of practice. Suppose we have

$$\frac{39}{52}+\frac{45}{90}+\frac{16}{48}$$

Before finding the L. C. D. we see if the terms can be reduced. The first figure of the numerator of the first term is 3. Try if 3 will divide into top and bottom. It will go evenly into 39 but not into 52. It goes into 39 exactly 13 times, which shows that 13 will go into 39 three times. Will 13 go into 52? Trial shows it does exactly 4 times. Then divide 13 into numerator and denominator and we get instead of $\frac{39}{52}$ the simple fraction of $\frac{3}{4}$.

The next term can be seen at a glance; 45 will go into both numerator and denominator, and the fraction becomes $\frac{1}{2}$. The same with the third term; 16 goes into both and the fraction becomes $\frac{1}{3}$, and the whole sum becomes

$$\frac{3}{4}+\frac{1}{2}+\frac{1}{3}$$

the L. C. D. of which we can see is 12. There are several ways which make it easy to see if a fraction can be cancelled. If the last figure of either term is 5 or a multiple of 5, it can be cancelled by 5 or a multiple of 5. Thus $\frac{125}{325}$ can be divided by 5, giving $\frac{25}{65}$ which can be again divided by 5, giving $\frac{5}{13}$ which is the lowest term. Suppose the number is $\frac{84}{156}$. We can see at once that 12 will divide into both these terms, giving $\frac{7}{13}$. If the division cannot be seen at first, try a smaller number. Two goes into both terms, so try if 4 will go. It will go, giving $\frac{21}{39}$. We see at one that 3 will go into 21 and 39, giving the final result $\frac{7}{13}$. The simplest way is to divide by a small number first, and if it will go, try multiples of that number mentally till the highest one that will divide is reached.

Multiplication of Fractions

We can now proceed to consider the operation of multiplication, and we shall see as we proceed that the simplifying by cancellation can be well carried out in this work. Multiplication of fractions in no more difficult than multiplication of ordinary numbers. The operations are practically the same. We say twice times one are two, and in just the same way we can say twice times one half are two halves, or three times one third are three thirds. We might explain here that a whole number can be expressed as an improper fraction by making the whole number the numerator, and the denominator unity thus: $\frac{2}{1}=2$; $\frac{3}{1}=3$. In practice the denominator is usually understood, as it is of no effect. Let us illustrate what we have just said. In expressing three times $\frac{1}{3}$ are one, we would put the statement down as follows: $\frac{1}{3}\times\frac{3}{1}=\frac{3}{3}=1$. The method is to multiply all the numerators together, the product being the numerator of the fraction representing the solution. The denominators multiplied together form the denominator of the solution. Thus above we see the numerators multiplied together $1 \times 3 = 3$ and the denominators $3 \times 1 = 3$, which makes a fraction with an equal numerator and denominator or a whole number. Now, taking this same expression $\frac{1}{3}\times\frac{3}{1}$ we can simplify it by cancellation.

In multiplying fractions, any numerator can be divided into any demoninator, or any denominator into any numerator, to simplify the expression before the multiplication is performed. This point should be fully grasped as it makes all operations with fractions very simple.

Take our simple sum $\frac{1}{3}\times\frac{3}{1}$.

The denominator of the first term will divide equally into the numerator of the second term, which makes the whole expression become $\frac{1}{1}$. Now in practice we would not write it this way but in this form $\frac{1\times3}{3}$, the denominator 1 being understood. It does not affect the result in any way. We might also write it $\frac{1}{3}\times3$ which is the same thing. Any of the three expressions, $\frac{1}{3}\times\frac{3}{1}$, $\frac{1\times3}{3}$, or $\frac{1}{3}\times3$ mean the same thing exactly.

Now the above is a fraction multiplied by a whole number. Let us take a fraction multiplied by another fraction $\frac{1}{2} \times \frac{3}{4}$.

Proceed as before. Multiply the numerator $1 \times 3 = 3$. Multiply the denominators $2 \times 4 = 8$. The work would appear $\frac{1}{2} \times \frac{3}{4} = \frac{3}{8}$, or else, which is more convenient, make the line which divides numerator and denominator a continuous one, thus $\frac{1\times3}{2\times4}=\frac{3}{8}$.

Now let us take several fractions and multiply them together. Take anything we happen to think of, say

$$\frac{1}{2},\ \frac{3}{16},\ \frac{7}{8},\ \frac{14}{32},\ \frac{28}{20}$$

Put them down like this

$$\frac{1\times3\times7\times14\times28}{2\times16\times8\times32\times20}$$

Now see if any numerators or denominators will divide into each other, or if any number will divide both a numerator or denominator. None of the numerators will divide into a denominator, but one denominator will divide into a numerator, and it is possible to reduce some of the terms by division. To make is simple, let us put them down separately again.

$$\frac{1}{2}\times\frac{3}{16}\times\frac{7}{8}\times\frac{14}{32}\times\frac{28}{20}$$

(1) $\frac{1}{2}\times\frac{3}{16}\times\frac{7}{8}\times\frac{\overset{7}{14}}{\underset{16}{32}}\times\frac{\overset{7}{28}}{\underset{5}{20}} = \frac{1029}{20480}$

(2) $\frac{1}{2}\times\frac{3}{16}\times\frac{7}{8}\times\frac{14}{\underset{8}{32}}\times\frac{28}{20} = \frac{2058}{40960} = \frac{1029}{20480}$

(3) $\frac{1}{2}\times\frac{3}{16}\times\frac{7}{8}\times\frac{\overset{7}{14}}{32}\times\frac{28}{20} = \frac{1176}{81920} = \frac{1029}{20480}$

(4) $\frac{1}{2}\times\frac{3}{16}\times\frac{7}{8}\times\frac{\overset{7}{14}}{\underset{8}{32}}\times\frac{\overset{7}{28}}{20} = \frac{1029}{20480}$

Take each term separately. The first term cannot be reduced. neither can the second or third. The fourth and fifth we see at once can be. The fourth term can be divided by 2, and the fifth by 4, or we might divide the denominator of the fourth term and the numerator of the fifth term by 4. Always remember that if either a numerator or a denominator is reduced, a denominator or numerator to correspond with it must also be reduced. Dividing a numerator into a denominator, or vice versa, is always correct, providing the divisor is cancelled when the dividend is cancelled; but in reducing by outside divisors as we have just suggested, care must be taken to ensure that both a numerator and denominator are reduced at the same time. Let us illustrate this point.

First, cancelling the fourth term by 2 and the fifth by 4.

Second, cancelling the denominator of the fourth term and numerator of the fifth term by 4.

Third, by cross cancellation, and fourth cross cancellation, and cancelling one numerator and one denominator by 4.

The final result of the second sum is further cancelled by 2, and the third by 4.

Take a simpler case:

$$\frac{3}{4}\times\frac{8}{6}\times\frac{12}{9}\times\frac{\overset{2}{24}}{16}\times\frac{18}{24}$$

$$\frac{3}{4}\times\frac{\overset{4}{8}}{6}\times\frac{\overset{4}{12}}{9}\times\frac{\overset{2}{24}}{\underset{2}{16}}\times\frac{\overset{3}{18}}{\underset{2}{24}} = \frac{6}{4} = \frac{3}{2}$$

The second line shows how it would appear after cancelling.

There has not been a single multiplication operation in solving this problem. It has all been done by cancellation, and it is surprising how often this can be done in actual problems. It saves time, and also makes for accuracy. For instance, in a calculation frequently occurring in boiler work we get an expression of this kind, which can be reduced like this.

$$\frac{5\times5\times22\times2\times2\times16}{8\times8\times28\times1\times5\times5}$$

$$\frac{\overset{1}{\cancel{5}}\times\overset{1}{\cancel{5}}\times\overset{11}{\cancel{22}}\times\overset{1}{\cancel{2}}\times\overset{1}{\cancel{2}}\times\overset{2}{\cancel{16}}}{\underset{4}{\cancel{8}}\times\underset{1}{\cancel{8}}\times\underset{14}{\cancel{28}}\times1\times\underset{1}{\cancel{5}}\times\underset{1}{\cancel{5}}} = \frac{11}{14}$$

The rule to remember for multiplication of fractions is: First reduce all fractions to their lowest terms. Multiply all the numerators together for the new numerator, and all the denominators together for the new denominator.

Division of Fractions

The division of fractions is simply a repetition to a large extent of the multiplication of fractions. However, there are some points to observe that are different. If we wish to find out what number represents a fraction of a whole number, we multiply the number by the fraction. For instance, if we want to know the number representing ¾ of 2, we multiply $2 \times \frac{3}{4} = \frac{6}{4} = \frac{3}{2} = 1\frac{1}{2}$.

Now we really have divided into four parts and have then taken three of these. But suppose we wish to find out how many times ¾ is contained in 2.. We must divide ¾ into 2. To do this, we must first find how many quarters there are in 2 and divide that number by 3. Now we know that there are 4 quarters in 1, and in 2 there are $4 \times 2 = 8$. 8 divided by $3 = \frac{8}{3} = 2\frac{2}{3}$. Now, if we set this down in the ordinary way it would appear as $\frac{2 \times 4}{3}$, or $\frac{2}{1} \times \frac{4}{3}$. When we multiplied by $\frac{3}{4}$, our sum was $\frac{2}{1} \times \frac{3}{4}$. When we divide by $\frac{3}{4}$, the sum is $\frac{2}{1} \times \frac{4}{3}$.

Hence the rule for division of fractions: Invert the divisor and multiply.

Let us take an example: Divide $\frac{7}{8}$ by $\frac{15}{16}$. Invert the divisor and multiply, the statement becoming $\frac{7}{8} \times \frac{16}{15}$. Now 8 will cancel into 16 and the sum becomes $\frac{7 \times 2}{15} = \frac{14}{15}$. Similarly take $\frac{2}{3}$, divided by $\frac{12}{18}$. We get $\frac{2}{3} \times \frac{18}{12}$ which by cancelling becomes $\frac{6}{6} = 1$. Take:

$$\frac{14}{16}\times\frac{13}{12} \div \frac{7}{8}\times\frac{8}{10}$$

This is an example of a compound fraction, and means that the product of the first two terms should be divided by the product of the last two terms. It could also be stated thus:

$$\frac{\frac{14}{16}\times\frac{13}{12}}{\frac{7}{8}\times\frac{8}{10}}$$

or thus:

$$\frac{14}{16}\times\frac{13}{12} \Big/ \frac{7}{8}\times\frac{8}{10}$$

They would all mean the same thing. Let us take the first statement:

$$\frac{14}{16}\times\frac{13}{12} \div \frac{7}{8}\times\frac{8}{10}$$

This becomes $\frac{14}{16}\times\frac{13}{12}\times\frac{8}{7}\times\frac{10}{8}$, which by cancellation boils down to $\frac{13 \times 5}{6 \times 8} = \frac{65}{48}$.

In the second statement:

$$\frac{\frac{14}{16}\times\frac{13}{12}}{\frac{7}{8}\times\frac{8}{10}}$$

we can cancel out to begin with and our statement becomes:

$$\frac{\frac{13}{16 \times 6}}{\frac{1}{10}}$$

which is:

$$\frac{13 \times 10}{16 \times 6} = \frac{130}{96} = \frac{65}{48}$$

(Continued on page 239)

The Theory and Practice of Electricity

In These Articles the Theory Will be Developed Sufficiently to Enable the Practical Man to Grasp the Underlying Principles of Apparatus Under His Care, Both Direct Current and Alternating

W. F. SUTHERLAND

WHILE a knowledge of these things will not perhaps help an engineer in the operation of his plant yet they are of deep interest and help in the understanding of the more practical side of electrical science. This first article then will be devoted to a discussion of some of the simpler facts relating to this newer development in scientific knowledge and from this we can go on to the extremely practical power plant problems.

What is known as matter, iron, wood, any substance whatever, is supposed to be made up of an almost infinitely large number of small units called atoms. The theory which is called the atomic theory has been a development of the last century or so and in itself it explained a great number of facts about the world in which we live. There are supposed to be about 92 kinds of these atoms and from this small number all of the countless substances and materials existing are built up. Two tons of different kinds combine and produce a third substance differing from each. It is assumed that these atoms are very small and in fact their size has been estimated and even measured from certain experiments. It has been said that if a drop of water were enlarged to the size of the world each atom would be the size of a baseball.

In passing when two or more atoms hook up together the resulting unit is called a molecule and the molecule as a whole is what determines the properties of the particular substance.

For a long time it was held that atoms were indivisible, that is they were the smallest possible units into which matter could be divided. All this has been changed and this is where electricity enters into it and plays a most important part, for it is now held and is a generally accepted fact that the atom, and in consequence all matter is nothing more nor less than electricity.

That is rather an interesting statement for when it is examined closely the reader is forced to come to the conclusion that matter is not such a substantial thing after all. This is much more apparent when the theory is more closely examined in what follows.

Let us take the atom and look into its make up. Every atom is now supposed to consist of very small units of electricity of two kinds. Just as man and wife exist together and to outward appearances at least in harmony, so two kinds of electrical units or while not strictly correct we may say particles exist together in the atom and in their effects exactly balance each other. These two types are called positive and negative electrons, electrons being the name given to them to show that they are of an electrical nature.

It is further supposed that the positive unit is placed at the center of the atom and that the negative units are placed around it in space, in such a way that the force of repulsion and attraction between the negative and positive units exactly balance or nearly so.

Thus we can have four negative electrons placed at the corners of a cube with one positive nucleus in the center.

The properties of the elements, their comparative weight, their chemical activity, their electrical characteristics, in fact every property they possess is dependent upon the number of electrons in their atoms. Further the number of electrons is fixed for each element and when it loses one permanently it is no longer the same element but another one.

Thus radium by the loss of electrons is very gradually changing into something very much like lead and in doing so liberates anoher element, helium. The old idea of the fixed and unchanging nature of the elements is thus no longer true and it is supposed by some that they all are changing into others lighter than themselves.

It is now possible to predict how any given element will behave, solely from a knowledge of the numbers of electrons in its atom,—whether it will be a gas, liquid or solid at ordinary temperatures, whether it will conduct electricity or not, whether it will be active chemically or not and many other properties.

These little electrons are also called into play to explain the flow of electricity through wires for in them seems to be the explanation. It is thought that this flow is nothing but a flow of electrons from one atom to another or along the wire at a very high velocity. The theory also offers some possibilities in the explaining of magnetism.

It may be of interest to compare the size of the electron with that of the atom. If we took an atom and enlarged it until it had a diameter of one mile then the electrons in it would be about five feet in diameter while the nucleus would only be about the size of a pinhead. These things have all been calculated out with minute care and while some of them are open to modification yet in the main the theory is a harmonious, well knit structure capable of explaining nearly everything to which it is applicable.

Ever since some of the ancient philosophers first noticed that amber jet and other substances attracted bits of straw leaves and feathers, speculation has been rife as to the nature of what we now call electricity. It is only within the last few years owing to the advance in knowledge and the progress made in other branches of science that any real knowledge of electrical phenomena has been realized. And while the old saying that "we do not know just what electricity is," is as true to-day as ever scientists have a suspicion that they know a good deal about it and if they cannot explain electricity itself they can at least explain very nearly everything else in terms of electricity.

It is further possible to explain such widely differing things as chemical reactions, the action of radium and other similar elements, wireless telegraphy and even the constitution of matter itself in terms of one simple theory which covers pretty nearly the whole field of physics and chemistry.

It is seen from the above that matter is very much like a seive in structure and that it consists of scattered electrons and positive nuclei with spaces in between them comparable to the distance between the earth and the moon reduced to the same scale in between.

The ever curious human mind won't be satisfied in getting the thing down to this point and will ask next "What are the electrons or units of electricity made of?" This is where a good deal of discussion has arisen, and it is supposed by some that an all pervading fluid substance or medium exists to which the name of ether is given. In this and through it we receive light from the sun and wireless messages from Europe. It is also supposed to be at the root of the electron for the electron is supposed to be an ether strain. As a very crude analogy and on probably not at all in accordanace with facts one might suppose a bubble of compressed air to exist in the midst of a lump of jelly. It would exert a stress on the jelly and deform it. In the same way a strain is supposed to exist in the ether giving rise to an electron.

It is truly a most remarkable theory which will at once explain the constitution of matter, the nature of electricity and very nearly every physical and chemical phenomenon of which we are aware.

Some Fundamental Principles

While the nature of electricity and many of its relations to matter will always possess a fascination for the human mind, the engineer is more concerned with its practical applications and this series of studies will be confined almost solely to practical power plant problems. Before these are taken up it will be well

to dwell for awhile upon some of the elementary principles underlying the whole theory of power generation.

These principles apply equally well to the steam power plant and to every other prime mover or source of energy and once a clear conception of the differences existing between and the meanings of the terms work, energy and power are obtained, the initiation into electrical theory will come very easily.

Force

The idea of a force is familiar to all of us, a weight resting on a table exerts force upon it, we exert force upon whatever we are standing on, water in a dam exerts force upon it, compressed air in a tank exerts force upon the tank. In this country at any rate we usually speak of force as being measured in pounds,—that is a weight exerts a force of so many pounds upon the table upon the string or rope to which it may be attached.

This is all right so far as it goes but we can find another expression which conveys something further to our minds. If we have a weight of 100 lbs. supported by a rope or cable of 2 sq. inches area we can divide the figure denoting weight by that denoting area and call the result so many (50) pounds per sq. in. That is, an expression has been found which tells us the relation between the weight supported and the size of the supporting member. But we still have the idea of a simple force and it is quite in order to speak of the total force acting on a body or a portion of it expressed, say in pounds per sq. inch.

There is another unit which enters into many engineering calculation —length or distance and this can be combined with the idea of a force to obtain something totally different—work. If a weight of three pounds is lifted through a height of four feet, for example, what we call work has been done on the weight and it is possible to find an expression telling just how much work has been performed. Two things enter into this expression, the weight lifted and the distance through which it has been raised. So if the weight in pounds is multiplied by the height in feet a figure of $3 \times 4 = 12$, in this case, will be obtained and to it is given the name of foot-pounds.

Work always implies the idea of a force acting through a distance and in the English language the name given to it expresses this relation clearly—foot $\times$ pounds or foot-pounds. Occasionally the engineer runs across an expression for work given in foot-tons or in some similar fashion but this idea is clearly implied.

Occasionally the engineer or student runs across the word (Joule) in his reading. This is another name for work and is taken to mean 0.7373 ft. pounds. It is thus a name given to a certain definite number of foot-pounds and has a very simple relation to some of the electrical units denoting work. It will be taken up later on in this course of studies.

While weight can in general be considered as a force, all forces are not due to the weights of bodies or substances and are not measured in terms of the weights of the bodies acting.

For instance consider Fig. 1. A table supports a large block of iron substance and to this block a string is attached, leading both ways over pulleys to two scale pans, one on each side. It will be readily seen that the one scale-pan balances the other and the block has no tendency to move. If now a number of weights are placed in one of the scale pans until the block begins to move a certain force will be exerted on the block and its magnitude will be exactly given by the weights themselves and not by the weight of the block.

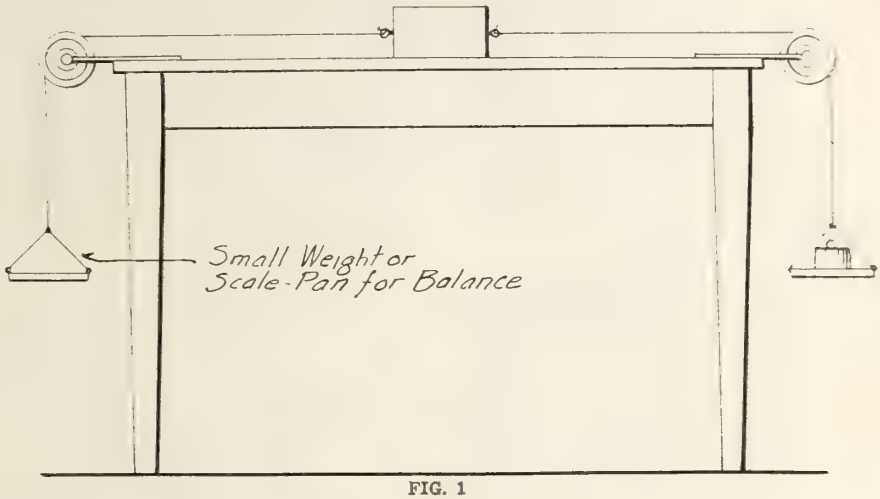

FIG. 1

If by this means, the block is moved say two feet by a weight of three pounds $2 \times 3 = 6$ foot pounds of work will have been done. The same amount of work will have been done by merely pushing the block along by hand or by pulling on the string.

Energy

Work and energy are very often confused even in the minds of those who by training ought to know better. Both are measured in foot-pounds and are mutually convertible.

If a man were to lift a weight of 10 lbs. from the floor to a table through a distance of three feet, he would be doing work to the extent of thirty foot-pounds. This work has disappeared and has appeared in the body in the form of increased energy. For the weight has been elevated in position and by this very fact it is capable of doing work in its turn. If it were pushed off the table and onto the floor it would in its turn do thirty foot-pounds of work on the floor, to its damage no doubt.

When the weight was at rest on the table it would be said to possess thirty foot-pounds of potential energy, that is energy which could be called forth at will. At the instant when it was pushed off the table it still possessed this amount of energy in the same manner but just before it reached the floor, while still again possessing as much energy as before, the form in which the energy existed had changed. At this instant its energy would be solely due to its motion and to this form of energy the name "Kinetic" is given, that is energy due to motion.

In falling the potential energy decreases and the kinetic inceases while at the instant of striking both vanish and are converted into work. The same reasoning can be gone through in respect to Fig. 1. Suppose the block on the table were at the left hand side of it and the right hand scale-pan were at the top. If a weight just sufficient to move the block were now placed in the scale pan it would fall pulling the block after it. When the block came to rest at the end of its travel the weight would be in its lowest position and all the work done at the expense of the energy of the weights would have been spent in the moving of the block. In this case the potential energy of the weights has been gradually used up in moving the system, in overcoming friction and the sum total of the energy has been similarly decreasing throughout the travel.

While energy thus may be expressed in terms of the force in general or by weight or mass, and by the distance through which the body falls or could fall, certain mechanisms do not permit of a ready calculation of this quantity in these terms directly. Such is the case of a flywheel or other rotating body which acts as a store of energy. In this case we have a body possessing weight and also possessing velocity. In this case it is possible to find out the energy possessed by the different portions of the wheel by multiplying their mass into the distance through which they would fall to arrive at the same velocity which possess by reason of their rotation. The sum of these quantities gives the energy possessed by the flywheel as a whole.

Portions of a flywheel remote from the axis possess more energy for the same weight than do portions nearer the axis since their velocity is greater.

Power

Power is often confused with work and with energy but it is open to simple

Chart of the Torsional Strength of Shafts

By the Use of the Accompanying Chart the Figuring of the Strength of Shafts is Made Comparatively Easy. Much Time Can be Saved Over the Laborious Use of Mathematics

By JOHN S. WATTS

THE accompanying chart will be found useful in determining the diameter of a shaft required to carry a given torque or torsional moment at any stress from 4,500 to 12,000 pounds per square inch.

To use the chart, simply follow along the horizontal line for the required torque and read off the diameter of the shaft on the diagonal line that intersects this horizontal line at the vertical line for the stress decided upon.

For example, the diameter of shaft required to carry a torsional moment of 120,000 inch pounds at a stress of 6,500 pounds per square inch, will be 4 9-16 in.

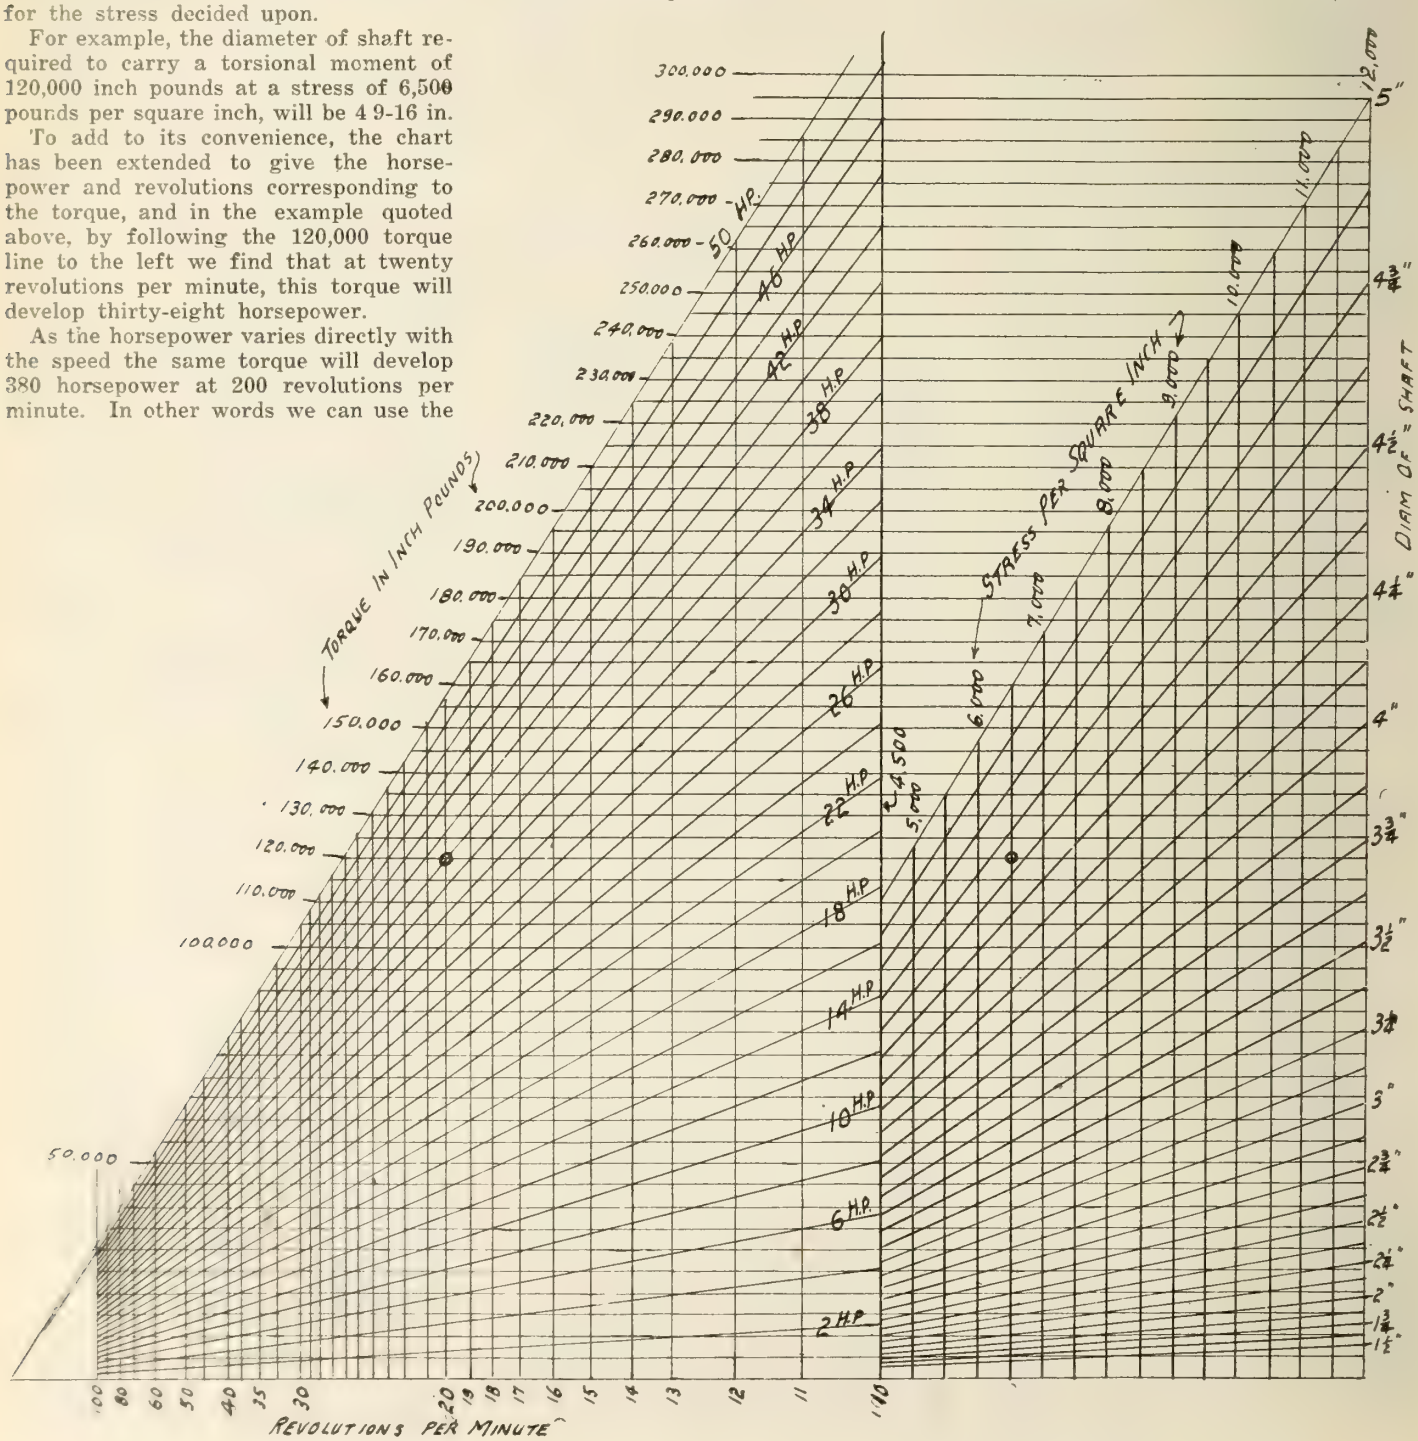
To add to its convenience, the chart has been extended to give the horsepower and revolutions corresponding to the torque, and in the example quoted above, by following the 120,000 torque line to the left we find that at twenty revolutions per minute, this torque will develop thirty-eight horsepower.

As the horsepower varies directly with the speed the same torque will develop 380 horsepower at 200 revolutions per minute. In other words we can use the chart for horsepowers and speeds above or below its range by simply dividing or multiplying the horsepower and the speed by ten, or any other convenient figure.

This enables us to use the chart to determine the size of shaft (up to 5 in. diameter) required to transmit any horsepower at any revolutions per minute, when the horsepower is given instead of the torque.

The chart will also be of material assistance in calculating geared or belt-drives, to transmit a given horsepower at a given speed as from the intersection of the horsepower and revolutions lines we read the corresponding torque, which, being divided by the radius in inches of the gear or pulley, will give us the load in pounds, to be transmitted by the teeth of the gear or by the belt.

It should be remembered that if the



gears or pulleys on the shaft are not close up to the bearings, a bending stress will be added to the torsional stress, and the shaft must be increased in diameter to take care of this additional stress.

The lowest stress, 4,500 pounds, should be used when the load is constantly reversing in direction and is suddenly applied.

A stress of 9,000 pounds may be used when the load is gradually applied, without shock and gradually reversed.

The maximum stress of 12,000 pounds is allowable only when the load is steady, does not reverse, and is applied gradually without shock.

A description of the method used in constructing this chart may be of interest and a help in making up other charts for solving similar problems.

First, we lay off the horizontal lines for the torques to a convenient scale, in this case 1 in. equals 40,000 inch pounds, and calculate the torsional strength of each diameter of shaft at the maximum stress, 12,000 pounds per square inch, by the formulae

$$T = \frac{\pi}{16} fd^3$$

and mark points on the torque scale to indicate each diameter at the points corresponding to the strength so calculated.

Now the maximum stress being 12,000 pounds per square inch, we measure along the base line, to the left, a distance equal to 12,000 to any scale, in our case we have chosen ⅜ in. = 1,000, and draw the diagonal lines for each diameter to this point.

Measuring back from this same point, distances equal to 4,500, 5,000, 5,500, etc., etc., and erecting vertical lines at each point, it is obvious that the height of each of these vertical lines to its intersection with any diameter diagonal line will be equal to the torsional strength of that diameter of shaft at that stress for which the vertical line is marked.

Now, coming to the triangle at the left, we calculate the torque which will be developed at ten revolutions per minute by fifty horsepower, by the following formulae:

Let T = torque in inch pounds.

$$\text{Then h.p.} = \frac{T \times \frac{2\pi}{12} \times \text{r.p.m.}}{33{,}000}$$

$$\therefore T = \frac{\text{h.p.} \times 33{,}000}{\frac{2\pi}{12} \times \text{r.p.m.}}$$

Marking this point on the torque scale on the central vertical line we have the point corresponding to 50 horsepower, and by dividing this height into twenty-five parts we get point for the torque corresponding to each increment of 2 horsepower up to 50 horsepower at ten revolutions per minute.

We now make the base line of the left-hand triangle ten inches long (to a scale of half size in the chart) because ten is the number of revolutions we assumed for the calculation of the horsepower on the central vertical line.

Now, as the torque is proportional to h.p.
the —, we scale back to the right from r.p.m.
the end of the base line, distances equal
to $\frac{10}{100}$, $\frac{10}{90}$, $\frac{10}{80}$, $\frac{10}{70}$, etc., the denominator
of these fractions being the revolutions per minute in each case, and raise vertical lines at each point so marked.

It can be seen that the height of any of these vertical lines to its intersection with any horsepower diagonal line will be proportional to the torque delivered by that horsepower at that number of revolutions.

THEORY AND PRACTICE OF ELECTRICITY

Continued from Page 237

explanation and should present little difficulty to anyone who cares to devote a little thought to it. We have seen that in the defining of work we had two quantities to consider force and distance. In considering power a third quantity, time, is introduced.

Thus it is conceivable that one man could lift a bucket of water from a well twice as fast as another, by virtue of his superior strength. In both cases the energy required and the work done are the same but the time varies. The first man is twice as strong and has twice the power. The familiar term horse-power originally devised by James Watt to measure the power or strength of his engines includes all three things, force, distance and time in its composition. One horse-power means 33,000 ft-pounds of work done in one minute. To find the horse-power that any mechanism is capable of exerting it is only necessary to find the amount of work done in foot-pounds and divide it by the time in minutes and by 33,000.

Thus supposing the man at the well lifted 50 lbs. of water and bucket through a distance of 60 feet in 4 minutes. Then the number of foot-pounds of work done would be $50 \times 60 = 3{,}000$ and since this is done in 4 minutes the horse-power would be $3{,}000 \div 4 \div 33{,}000 = 1\text{-}44$ or 0.0227.

It will be well to summarize the definitions of these different units as follows:

Work—Force by distance.

Energy—Force by distance through which the body could fall or through which it would fall to achieve the same velocity it possesses.

Power—Time rate of doing work, i. e. force by distance divided by time.

COURSES OF INSTRUCTION

Continued from Page 235

The third statement:

$$\frac{14}{16} \times \frac{13}{12} \quad | \quad \frac{7}{8} \times \frac{8}{10}$$

becomes at first glance:

$$\frac{14}{16} \times \frac{13}{12} \times \frac{10}{7}$$

7 cancels into 14, leaving 2 which cancels into 12, leaving 6. 2 will go into 16 and 10, leaving 8 and 5. The final results is: $\frac{13 \times 5}{8 \times 6} = \frac{65}{48}$.

Before going into the study of complex fractions, we will go over in the next article the meaning and use of the various signs employed, and then take up some complicated examples of fractions.

To Take up Civil Engineering—Due to recent amalgamation placing them in a very favorable position for carrying out large contracts, Messrs. Armstrong Whitworth of Canada have decided to enter the public works contracting field. The new development will be under the control of Mr. Robert H. Mackenzie.

Big Power Contract Let—The Nova Scotia Power Commission at a recent meeting let the contracts for the St. Margarets' Bay Power Development. The contract for the four electric generators went to the General Electric Co., and will be built in their shops at Peterborough. The Pacific Coast Pipe Co. of Vancouver were awarded contracts for wood stave pipe 6 feet and 10 feet diameter. The general construction contract, including the building of power houses, dams and intakes, were awarded to D. G. Loomis & Sons, Montreal.

The American Waterworks Association will hold its 40th annual convention in Montreal from June 21 to 24, with headquarters at the Windsor Hotel, the Windsor Hall being reserved for an exhibition display, where many American and Canadian manufacturers of waterworks equipment will have exhibits. The meeting will bring many prominent hydraulic engineers from many points of Canada and the United States, and it is expected that about 1,000 delegates will be in attendance. Extensive plans are now in preparation for the professional meetings and entertaining features. H. G. Hunter, of Montreal, is the chairman of the entertainment committee

The Administrative Commission of Montreal are again proposing that the City Council accept their suggestion for the adoption of a by-law relative to the compulsory installation of dry sprinklers in the basement of all public and other large buildings. The first suggestion as originally drawn up included dwelling houses, but in the revised form this class of building has been exempted. The purpose is to provide more adequate facilities for fighting fires where the nature of the material would produce noxious gases and suffocating fumes: the proposed method enabling the firemen to connect the hose and drench the interior without danger to themselves.

Delayed Certificates

WE HAVE received letters from a number of subscribers, who complain that they have not yet received their certificates, and fear that they cannot retain their positions on this account.

POWER HOUSE took this matter up with a member of the Board of Examiners, who explained the matter very clearly. In almost every case where delay in issuing certificates has occurred, it has been through the failure of the applicant to properly fill up the form of application. The chief neglect seems to be in making the affidavit, and the Board wish to call this strongly to the attention of applicants. The particulars of service and experience must be sworn to in order to be of use.

As regards the holding of positions, any man holding a position before the passing of the act may continue to hold it, irrespective of grading. If he wishes to move to another plant to take charge, he must obtain a certificate of the necessary class to cover it.

While Power House is anxious to give all the help possible to our readers, we would remind them that on matters of delayed certificates, grading, etc., they will get much more satisfaction by applying direct to the Board, the members of which are anxious to administer the act in a fair and equitable manner, and to the best interests of the engineers themselves.

Technical and Practical

FOR some time back we have had an animated correspondence in our columns on the merits and demerits of the graded certificate act, with slight diversions into the realms of philosophy, literature, the use of slang and other interesting bypaths. The term that seems to occasion much argument is the one so freely and glibly used, "technical man."

Now, one cannot point out a certain man, and say simply that man is a technical man, and point out a second man, and say this man is not a technical man. The first man may possess more technical knowledge than the second, it is true, but a third man may easily possess technical knowledge greater than the first two combined. They are all technical men. Technical knowledge runs all the way down from the men in the highest rank such as were Faraday, Rankin, Joule, or in later days Kelvin, Edison, and their contemporaries, to the newest student of a correspondence or technical school. From the highest to the lowest, all possess some degree of technical knowledge, and it is the difference in degree that makes the value of the man, in either the commercial or scientific field. As soon as a green hand enters into the boiler room, and masters the uses and names of the various boiler mountings, he has acquired a certain amount of technical knowledge.

There are certain branches or stages of technical acquirements that can be attained only by those who have no other work in life but the pursuit of abstract problems. These men achieve results which are of benefit to the world in general. Placed in a commercial position they would most likely be dismissed as incompetents by an intensely practical management. Other men take the principles the investigators have discovered, and embody them in designs which are afterwards turned over to others to carry out. The machine is built, the idea has materialized, but its success in the last analysis will often depend on the man who operates it. His success will depend on how far he can go in understanding the idea of the man who first visualized the principle. That is he must have some knowledge of a technical nature, as well as being able to perform the task of starting and stopping.

There is nothing beyond the reach of any stationary engineer in acquiring a technical knowledge that will be of great value to him in his daily work. There are many men who wilt mentally when confronted with the necessity of acquiring technical knowledge. A grasp of the ordinary rules of arithmetic, a little application to study, and in a very short time the man who has always looked upon himself as being only a practical man, finds he has achieved a measure of technical knowledge.

It is engineers themselves who should spread this knowledge. Organisations like the C. A. S. E. have it in their power to do an enormous amount of educational work, a power that we fear is not used as it should be in every case.

We cannot all be Kelvins and Edisons, but we can all possess the requisite amount of knowledge to make us experts in the line of work we are engaged in, whatever it may be.

Steam for Power and Heating

IN THIS issue there appears an article by Mr. C. E. Stroymeyer, on the economy of engines used for power, the exhaust from which is used for heating. This should be carefully read by steam plant owners and engineers in Canada, where the heating proposition is such a big feature of plant operation. Mr. Stroymeyers name in the engineering world is of such standing that any statement he makes can be looked upon as authoritative, and the reader can be assured that there is no ulterior motive behind it.

Although writing of conditions in Great Britain, his

remarks apply equally to Canada. In large factories in this country, there is a heating load for purely room warming purposes which lasts over at least six months. This is entirely apart from heating used in process work, such as drying kilns, cleaning tanks, japanning ovens, glue heaters, and dozens of other processes where heat is required. This heat is necessary no matter how the power is secured, and if both power and heat can be secured from the one installation, there is a corresponding reduction of capital cost. When it is a question of buying power in the summer months, and using engines in winter, it requires very clear proof indeed to show that any saving can be made in view of the capital lying idle.

The point lies chiefly in the fact of whether the boilers are efficient or not. If the loss between the heat units contained in the coal and those transmitted to the water in the boiler is a minimum, then in the average factory it will be a very difficult job for the salesman of the central station to show where he can effect an economy. If the boiler efficiency is as low as it unfortunately is in many Canadian plants, the engineer is supplying the central station with an argument ready made.

During the war, when the Government were bestirring themselves somewhat over the question of saving coal, some electric power companies saw an opportunity to get into steam plants where their best efforts had hitherto been unsuccessful. We know of one case where after many prolonged interviews, and comparisons of figures, the factory management made the power company a proposition. The power company were to make the change, install the synchronous machinery necessary to keep up the power factor, and the rotary converter, etc. If after one year they could show a saving in fuel sufficient to justify the outlay, the factory would pay for the equipment, and continue to buy power. If this saving could not be shown, the power company were to put things back as they found them, and be out the expense. This offer finished the negotiations.

There are many small industries where heating is a minor matter, and price of coal, labor, etc., preclude the use of a steam power plant. On the other hand, in cases where steam is used in large quantities for process work and heating purposes, the self contained steam plant is more economical and more reliable than any outside power. The wide awake engineer and factory manager will have his power plant costs always available, so that he can instantly compare them with any offer he may receive from a philanthropic central power plant salesman who wants to save him money.

Couldn't Earn $2.80 a Day

HOW things hop! Could you go out to-day and hire a moulder for $2.80 a day? You might not be able to hire one at any price, but certainly $2.80 would never get a hearing.

A moulder had answered an ad. of a firm in an Eastern Ontario town. He was making $2.50 a day, and was willing to leave for $2.80. He so informed the wise man from the East, and here is what he received in return.

The letter is dated June 3, 1909:—

Dear Sir,—

Your favor of the 1st to hand. The two places are already filled in my moulding shop for which I was advertising.

The applications which I have received are rather amusing. Moulders now-a-days do not know what to ask in wages. I do not believe it is possible for you to earn $2.80 a day. If any one could I would pay it, but I know that no moulder under me has ever done that yet. Nor come near it. Our moulders have steady work, every day the year round.

The sequel to the whole thing is that only a few weeks ago the same shop was advertising for moulders again, the wording this time reading "Highest Wages Paid."

Chance For the Skilled Man

ACCORDING to officials whose business it is to keep in touch with the situation, the fuel situation in Ontario, as far as power is concerned, is decidedly bad now.

Every ton of coal should be made to do, as near as possible, the duty of a ton. Steam plants, even at their best, are some distance removed from 100 per cent. efficiency.

The shortage of coal—and it is not apt to be remedied very soon—calls for the elimination of the tinker and the guesser in every department of the business that is touched by the production or transmission of power.

Industry calls for men who know—know how to get the best results from the fuel used—how to get results in transmission—how to eliminate as much friction as possible.

Increasing costs call for the same thing.

There's a great chance now for the man who wants to take himself by his own shoe-strings and pull himself out of the rut.

He may have to burn the midnight oil to do it—or he may have to burn the midnight oil if he doesn't, trying to figure out how to make ends meet.

Industry has not become simply a case of automatic production. You may get this idea at times.

The man who is going to succeed is not the man who contents himself with looking after the machine.

The man who succeeds is the one who is keeping a few paces ahead of the machine.

The night classes, the technical papers and books are still the real stepping stones to men who want to get into that desirable class that are called in after the average man has failed to give results.

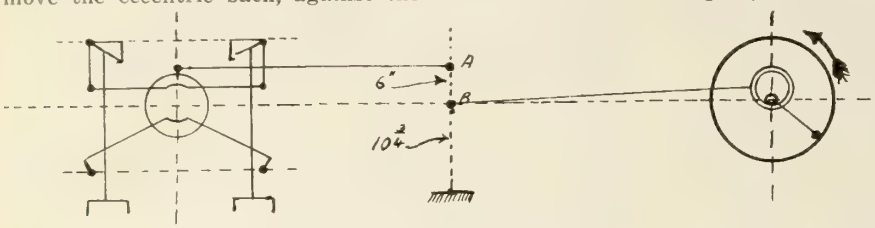
OUR QUESTION BOX

Questions are invited from readers regarding power plant operation and difficulties encountered

Question: The Corliss engine, outlined in accompanying diagram, is set to cut off at 1-5 stroke, and does not develop enough power. Can I make cut-off later? What effect will it have on the valve gear to move the eccentric back, against the



direction in which engine is running? By increasing the distance between A and B, to increase the travel of the wrist plate, would it make cut-off later and increase the power of the engine? Please explain action in all the valves.

Answer: The cut-off point in a Corliss valve is governed entirely by the knock off cam, which is actuated by the reach-rod from the governor. Lengthening or shortening this rod will move the cam on the bracket so as to release the hook either sooner or later. The limiting point of cut-off in an engine with this kind of gear is half stroke, but cut-off can be arranged at any position up to this limiting point. In the accompanying sketch it can be plainly seen that if the rod is lengthened, the knock-off lever which carries the knock-off cam, will be moved away from the latch hook which makes it have so much further to travel before releasing the hook, thus making cut-off later. Shortening will have the opposite effect.

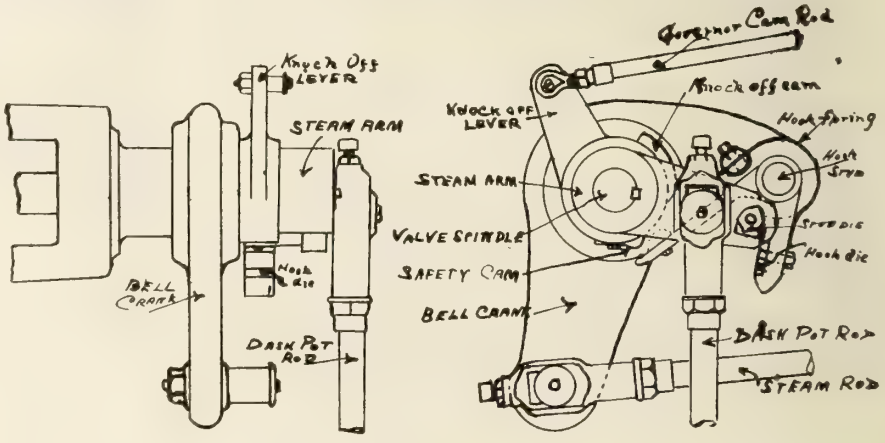
The effect of moving the eccentric, either by advancing or retarding it, will first affect the wrist plate movement. That is the part that is directly driven by the eccentric. Imagine the eccentric to have just 90 degrees advance, and the piston at the end of its stroke inwards. Then the centre line of the wrist plate would be vertical. Now if the eccentric is turned on the shaft, the effect will be to move the wrist plate off the vertical, either to the lead end or crank end of the cylinder. Now what will be the effect on the valves. Supposing that when the eccentric was at 90 degrees, and the wrist plate central, that the steam valves on the lead end was just on the point of hooking up. That is, whichever direction the crank moved, steam would be admitted as soon as the stroke commenced. Now the eccentric is moved ahead, the wrist plate will be moved ahead, and providing nothing else has been altered, the steam valve will be opened a small amount. Now the exhaust valve on the head end will, of course, be in the closed position, and the effect of this valve of moving the eccentric ahead will be to bring the edge of the valve closer to the part, which would make the valve open to exhaust earlier, and close earlier. So we see the general effect of moving the eccentric ahead will be to make the steam valve open earlier, and the exhaust valve open earlier and close earlier. The point of cut-off will be affected by moving the eccentric. If there were no governor knock-off cam, the cuh-off would be affected the same as all the other events, that is, it would be early.

Bringing the eccentric back will affect every event but cut-off, in the opposite direction, that is, it will make every event later. Taking our head end again with eccentric at 90 degrees and steam valve just on the point of picking up. Moving the eccentric back will move the bell crank lever further away from the die, so that it will have to travel further before picking up the valve, that is admission would be later. Cut-off, of course, would be late too if not made by the governor. The exhaust valve will have been moved so as to take the edge further from the port, making release later, and compression later. Generally speaking, advancing or retarding the eccentric of a Corliss engine has the same effect as it would in a slide valve engine, except in regard to cut-off. With the Corliss you have the added advantage of making independent adjustments of each valve after making the general adjustment.

Now our correspondent asks the effect of increasing the travel of the wrist plate.

Let us take again the eccentric with 90 degrees angle of advance, and crank at the inner centre. The steam valve is just about to open for admission. It will continue opening till released by the governor cam rod at the determined position of the stroke, and the remainder of the forward stroke of the wrist plate is lost motion as far as that valve is concerned. No matter how far the travel of the wrist plate is made, the period of admission is governed by the governor. The only point that might be gained is a slightly greater port opening due to the extra distance travelled while admission is taking place, and the one effect this would have would be to keep the admission line on the indicator card a little straighter, the gain of power being very very slight.

The effect on the exhaust valves of increasing the travel would be the same. The valve would travel a correspondingly greater distance in the same length of time as before. It might be necessary to alter the width of the bars, but generally there would be no gain. The engine is designed to perform the steam distribution with a certain length of valve travel, and giving it more will have but little effect unless carried to the extremes. Of course the point would have to be watched of the effect of the reach rods and hinge pins. You might cause the rod and lever to come in a straight line at some portion of the stroke, which would end in disaster.



Progress in New Equipment

THE MONO CO_2 RECORDER

Technical publications have printed hundreds of articles on combustion in which it has been repeatedly stated that an analysis of CO_2 alone is insufficient because the correct percentage of CO_2 varies with the kind of fuel used, the method of firing, the method of admitting air, etc. Thus in one installation 13 per cent. of CO_2 is the maximum that should be allowed. In another installation, 15 per cent. might be the maximum. In another 8 per cent.

The best way to be sure about it is to simultaneously keep tab on CO. It is highly important that no CO be present.

The Mono Corporation of America, 48 Coal & Iron Exchange, Buffalo, N. Y., now announces a recorder that enables the fireman to constantly see that no CO is present and that CO_2 is always maintained at a maximum.

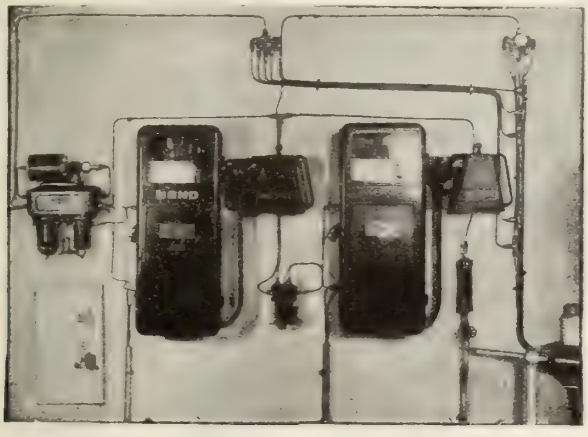


FIG. 1.

Bonus systems that have been based upon percentages of CO_2 have failed because the boiler room force soon learns how to so manipulate the dampers that a high CO_2 reading is obtained. Yet combustion is incomplete and the object of the bonus system is defeated.

Now that both CO_2 and CO can be recorded, the boiler room force finds it impossible to show an extremely high CO_2 without showing some CO. The fuel must be so burned that the percentage of CO_2 is as high as possible and at the same time there must be no CO. By so doing most economical combustion is effected.

The manufacturers of the Mono instrument have devised a premium system which they will be glad to explain to anyone interested. This system involves the use of a Mono rule which is laid over the chart. A record is kept on a sheet provided for the purpose and at the end of the month, the figures are added, the average determined, and the bonus is paid.

Fig. 1 shows the Mono Monoxide Recorder which will record both CO_2 and CO on one chart. The device shown at the left is called the "Monoxide Auxiliary Type K" or it is called the "Monoxide Supplement." It is this supplement which, coupled with the standard Mono CO_2 recorder, permits the recording of CO.

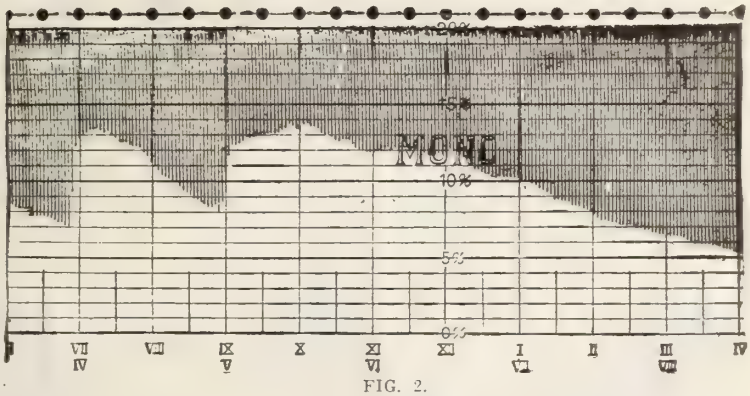

FIG. 2.

Fig. 2 shows a Mono CO_2 chart. Fig. 3 shows a Mono CO chart. When taken simultaneously, these charts of course give an absolutely accurate account of furnace conditions.

This same apparatus (without supplement) will record SO_2, hence it is a valuable instrument for use in pulp and paper mills.

The chemical field finds the apparatus valuable for the automatic analysis of nearly all gases: CO_2, CO, O_2, H_2SO_4, CH_4, N_2, etc.

The gas field finds the Mono instrument especially adapted to gas works for the determination of hydrogen, for carburetted water gas, and for carbon monoxide.

In fact, wherever gas is used to a great extent and where it is important that the gas be continuously, automatically, and accurately analysed, this instrument can be made to do the work.

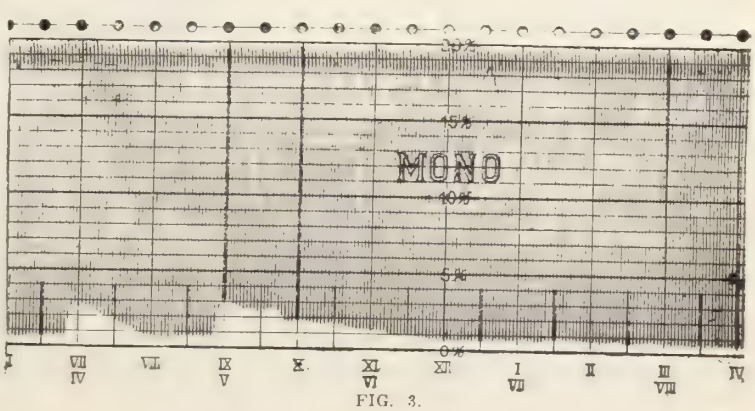

FIG. 3.

ROBERTS UNIT JACKS

The Roberts Mfg. Co., New Haven, Conn., handle a line of unit jacks and bolt couplers which should interest the mechanic in general. These jacks can be set to any height instantly by means of separate and interchangeable units. One merely builds up the proper number of units required and adjusts their rack jack. Lock joints connect each unit and are locked in place by means of a simple turn.

A surface gauge connection is also made, which can be clearly seen in the illustrations.

Readers can no doubt obtain all necessary details from a study of the various illustrations and will readily understand the advantages of such a system, especially for machine set-up work. All these jacks are made of first quality malleable iron, and will stand the strain placed on them in supporting work. These shop aids, as we might term them, are ideal for use on planers, vertical millers, horiontal mills, radial drills, boring mills, slotters, shapers, or in fact any machine upon which work has to be strapped in place. The erecting department will also find them of splendid service.

FROM LEFT TO RIGHT WE HAVE A TOOL-SETTING STAND, A LEVELING JACK, AND A SURFACE GAUGE CONNECTION.

THIS ILLUSTRATES THE LOCK JOINT. A SINGLE TURN FIRMLY LOCKS THE UNITS.

SOME EXTENSION UNITS AND RACK JACK.

This concern will also turn out what is known as an instant bolt coupler. By referring to the illustration showing work jacketed up and clamped, one can see a coupling in actual use.

This attachment is claimed to save the time and cost of making special bolts for special jobs. With the aid of coupler any length of bolt can be had by coupling up bolts you already have. Better still use studs for greater economy, for each bolt retains its own nut. These couplers are also made of malleable iron, and are designed to withstand high strains.

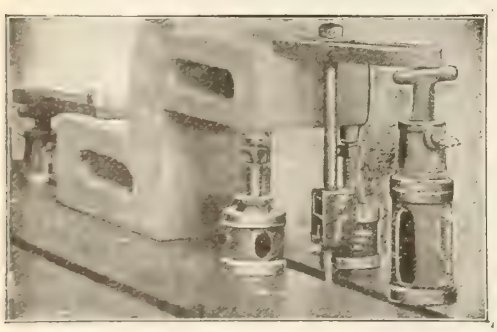

ILLUSTRATION SHOWING BOLT COUPLER AND JACKS IN USE.

HERE ARE THE UNITS. THEY CAN BE BUILT UP TO SUIT THE JOB.

The L'Air Liquide Society announce that their plant at London, Ont., is now in operation, and producing at full capacity. This is the seventh plant in Canada to be completed, and at present there are two others in course of erection, one of which will be in operation within a month of two. This news will, no doubt, be of interest to those requiring oxygen for use in their plants.

NEW PUBLICATION

Centrifugal pumps for sugar house service are described in Bulletin S, issued by the De Laval Steam Turbine Co., of Trenton, N. J. Centrifugal pumps are recommended for sugar house work because of their simplicity, reliability, high economy, wide range of capacity and small space requirements. There are no valves, and but two simple packings. The only parts subject to wear by rubbing are the bearings, the lubrication of which is automatic. Little attention is required, and inspection is easily made. De Laval Centrifugal pumps are characterized by horizontally split casings, by the fact that all parts are made to limit gages and are interchangeable, by comprehensive guarantees covering capacity, efficiency, and the relation between delivery and pressure, and by the fact that each pump is fully tested before leaving the shops. The present bulletin describes centrifugal pumps for handling raw juice, limed juice, soda, syrup, boiler feed water and injection water, and for maceration and hydraulic pressure service, etc. Motor and turbine-driven pumps, both single-stage and multi-stage, are illustrated and described.

The M. H. Detrick Company, of Chicago, Ill., has recently purchased the ash conveyor formerly manufactured by the Hagan Corporation, of Pittsburgh, Pa. The conveyor will be marketed hereafter under the name of the DETRICK-HAGAN CONVEYOR.

Steam Trap SARCO Saves Money in Six Ways

Saves money because it saves steam. Being operated automatically by the expansion and contraction of a volatile liquid, the valve is closed **promptly** when the condensation has been discharged.

2. Saves money by keeping the line free from **all** condensate **all** the time. The Steam Trap Sarco drains condensate as soon as it forms.

3. Saves money by returning condensate to the hot well while **still hot**, instead of when cold from lying around, as in bucket traps. This **hot** water can, of course, be much more quickly and economically re-converted into steam.

4. Saves money because it requires no platform building, no supports, no pit-digging. Steam Trap Sarco is so small and compact that it can be installed at any point in the line, no matter how limited the space, and becomes practically an integral part of the line.

5. Saves money because it has no complicated parts to require adjustment, repair or replacement. It eliminates entirely all the levers, gauges, floats, stuffing boxes and other superfluous parts found in traps of the bucket or float type. It has, in fact, only one moving part.

6. Saves money right at the start, because it costs but **one-third** as much as float or bucket traps. Its compactness and simplicity of construction is the reason back of its lower cost.

Steam Trap Sarco is made in sizes from ¾" to 3", for any given pressure up to 200 lbs.

You can try it out for yourself **at our expense** by taking advantage of our 30 days' free trial offer.

At any rate, send for Booklet J-15 and get the whole story of Sarco's greater effectiveness and lower cost.

SUPERHEATED STEAM IN TURBINES

It is generally estimated that the gain in economy due to the use of superheated steam is about 1 per cent. for every 10 deg. of superheat. Thus, if steam having 150 deg. of superheat is employed, the resulting gain should be 15 per cent., irrespective of whether the steam is employed in a reciprocating engine or a turbine. There are certain disadvantages which follow the improper use of super-heated steam, the two most important of these being the effect of high temperature on the castings of the engine, causing distortion; and the difficulty of lubrication. In the turbine the effects of distortion may be particularly serious in view of the fine clearances which have to be adopted with certain types of turbine, and it may be stated that one of the reasons why the high-speed impulse type of turbine is adopted is because with this type, owing to the high velocity of the steam, the clearances can be made more generous in both the axial and the radial direction. It is, however, advantageous to keep that portion of the turbine which is exposed to the effects of highly superheated steam as small as possible, and for this reason in the first set of nozzles the fall of pressure is often about two-thirds of the total fall between boiler and condenser, so that on leaving these nozzles the temperature of the steam has fallen to such a degree that its effects are greatly reduced.—"Shipbuilding and Shipping Record."

ANNOUNCEMENT

Geo. W. Cole, Limited, condensation engineers, Toronto, announce the opening of a new office in Montreal. It will be under the management of Louis H. Bacque, and will be situated at 76 St. Gabriel Street, Montreal. They announce at the same time the appointment of Mr. George A. Young, 203 Scott Block, Winnipeg, Man., as their representative for the prairie provinces.

CATALOGUES

We have received two well illustrated booklets descriptive of the products of the American District Steam Company. They describe respectively the heating system installed by this company, and known as the "Adsco" System, and heating specialties used with it. The system is operated on the atmospheric plan, pressure of only a few ounces being used. The catalogue is very complete, and includes rules for computing radiation required for any given temperature. The specialties include reducing valves, damper regulators, diaphragms, safety valves, pipe fittings, and all the necessary apparatus for a complete installation.

The Geo. F. Foss Machinery and Supply Company, of Montreal, has just issued an elaborate and well-arranged catalogue, containing 1,300 pages, exclusive of index, the latter occupying about 50 pages. The book is profusely illustrated with cuts and diagrams. A prominent feature of this catalogue is the arrangement of the various lines and the systematic grouping of the different articles. The illustrations on a given page are designated by the same number, being distinguished from each other by the addition of different letters. A special index has been devised for locating all articles described and instantaneous reference is practically assured. A considerable section in the back of the book is devoted to useful and valuable information.

The Jeffrey Manufacturing Company, of Columbus, Ohio, have issued a bulletin which is numbered 141 and which features their single roll coal crusher. This booklet contains interesting information regarding sizes of coal for stoker users and shows illustrations and drawings of a number of typical installations of crushers with other apparatus.

Montreal Gives Contracts.—The Administrative Commission of Montreal has awarded contracts for electric pumps and apparatus, in connection with the waterworks, to the following firms: The Fraser Chalmers Co., one 30,000 gallon pump at a cost of $50,250, one similar pump to the E. Laurie & Co. at a cost of $45,200. The Canadian General Electric Co. have been awarded contracts for manufacture and installation of transformers, motors, etc., at a cost of $48,640.

The Mono Corporation of America, with Mr. F. D. Harger as general manager, announces its location at No. 48 Coal & Iron Exchange, Buffalo, N. Y., to manufacture and sell the various types of Mono apparatus for the automatic analysis of CO_2, CO, O_2, H_2, SO_2, N_2, C_1, etc.

This company will maintain a service and inspection department in connection with their laboratory and will arrange for regular inspection trips among their customers.

The Precision Instrument Company has recently moved their factory to Newark, N. J., where they are located at 21 Halsey Street.

American Manufacturer Wants Representation in Canada

Our proposition should interest an established machinery supply house now calling on steam power plants in Canada. For particulars, write Box 518, Power House.

FAIRBANKS-MORSE

A National Institution of Mechanical Service

IN Canada, as in every country in the world, there are names which, through years of service, have warranted national confidence and good-will. In the Canadian world of mechanical and engineering efficiency there is one name which enjoys the distinction of leadership. Its prestige carries through the entire coast-to-coast chain of sales offices and warehouses into every city, town, and hamlet.

Fairbanks-Morse products mark the farmer, the manufacturer, the artisan, and all users as careful and practical buyers of mechanical goods. The Fairbanks-Morse 100% quality seal is the buying guide for the consumer—the guarantee of satisfaction.

The Canadian Fairbanks-Morse general catalogue is a reference of what is standard in design and practice in mechanical goods. This book lists the largest variety of scales, valves, steam goods, oil engines, pumps, electrical machinery, machine tools, woodworking machinery, transmission appliances, railway contractor's and machine shop supplies ever published in Canada in one book. Your copy will be sent on request.

Halifax, St. John, Quebec, Montreal, Ottawa, Toronto, Hamilton, St. Catharines, Windsor, Winnipeg, Regina, Saskatoon, Calgary, Vancouver, Victoria. 1

Canada's Departmental House for Mechanical Goods

TRADE GOSSIP

The Locomotive Superheater Company, 30 Church Street, New York, have issued a new bulletin, T-5. This bulletin covers the advantages of superheated steam. The context presents the engineering reasons for these advantages from a new angle. The argument is clear and concise and should be of interest to all power plant owners and operators in every industry or power plant service.

No Strike in Galt.—An amicable settlement has been reached by the iron moulders and manufacturers of Galt, and all possibility of a strike has been removed. The moulders demanded a wage of 80 cents an hour and an eight hour day, but after two joint conferences an agreement was reached whereby the minimum wage will be 72 cents an hour, an increase of 7 cents, and the week's work 48 hours.

The Homestead Valve Mfg. Co., of Homestead, Pa., announces the removal of its New York office to No. 242 Lafayette St., New York City. The new office is on the third floor and is several times the size of its former location; the removal having been found necessary, due to the expansion of its New York business. The New York office is in charge of Mr. P. L. Rhodes, who has with him Mr. William Gormly, Mr. John Gormly, Mr. George Nagle, Mr. C. A. Tyler and Mr. W. B. Goering.

Orders for Steel.—Important developments are expected from a survey which is now being made of the iron ore area at Lock Lomond and at other parts of Cape Breton. The examination is being made by a geological expert in the employ of the Dominion Steel Corporation. The Armstrong Whitworth Company, one of the largest shipbuilding firms in Great Britain, has been endeavoring to place an order for 20,000 tons of ship plate with the Dominion Steel Corporation here. The Government of New South Wales has also been negotiating for 15,000 tons with the Dominion Government. A total of 19,000 additional tons have been sold to other Governments.

Northern Electric Changes.—M. K. Pike, general sales manager of the Northern Electric Company, is now on a business trip to the branch houses, and will be absent from the head office at Montreal for six weeks. A. Dwight Smith, former sales manager of the Montreal district of the Northern Electric Company, has been transferred to the Montreal head office, and will have charge of train dispatching, fire alarm and marine supply sales. N. S. Richards, who, for the past three years, has been sales manager of the Calgary house, has been transferred to Montreal, and appointed sales manager of the Montreal district, effective June 1st.

Meet in Rochester.—Rochester, N. Y., has been selected by the general executive board of the International Association of Machinists as the convention city for the association this year. Toronto was longer under consideration as a convention centre, but apparently lost favor at the last moment. It will be recalled that the association endeavored to get certain grants, as well as facilities with which to make the convention an all-round success. The grant was not donated, although the facilities were offered. Rochester has apparently made the grant which Toronto refused to make. More than three thousand machinists will attend the convention, which is to be held next September, and it will last three weeks.

General Strike.—The Toronto "Globe" carries the following:—Executive officials of Local 152, International Union of Steam Operating Engineers, who met in the Labor Temple to discuss phases of the wage schedule which they expect to go into operation on June 1 in local plants, admitted that officials with the authority to call a general strike of the craft in Canada were now in Hamilton, where the local union is engaged in a fight with the Steel Company of Canada. They said that these officials had the power to call this general strike, which would paralyze industry in Canada, upon twenty-four hours' notice to all local unions. "There is a very serious unrest among members of the organization throughout the Province upon wages. We are the lowest paid of any skilled craft," said Business Agent Cummings, who stated that the international officers in Hamilton had not asked for an expression of opinion upon a sympathetic strike.

"SAFETY FIRST"

Bend the Spout
to suit position

Every requirement satisfactorily met with

ALL-WAY OILERS

SAVES TIME
SAVES OIL

Note the flexible spout. It enables you to oil all places — many places that previously could only be reached with force pump cans with specially bent spouts.

Indispensable to those who know. Will last as long as six ordinary oil cans. Saves 50% of oil bills.

Ask your dealer to show you the complete ALL-WAY line of oilers. If he cannot do so, please write to us.

ACT NOW!

You will be safe-guarded against boiler explosion due to low water, if you use VIGILANT REGULATORS. They cannot fail to operate and keep the water level where it will enable the boiler to produce the driest steam at the highest economy figures.

The slow uniform feeding of these regulators means fuel economy because the feed water is then heated uniformly to a higher degree.

Our instructive catalog will tell you more about the reason why the Vigilant will accomplish all that we claim for it, and more. Write.

D. K. McLaren Leather Belting

British Oak Tanned

Good Belting Cheapest in the End

The lowest priced belting is invariably the dearest. It does not give satisfactory service even when new—slips and is always thoroughly unreliable. A belt bought from the viewpoint of **service** is truly economical. The initial price may or may not be highest. **Learn what each is made of—and how.**

The Hide

The hides used in making D. K. McLaren's Leather Belting are cut from the backs of the choicest steers. The back is the strongest part and of even strength and elasticity through out.

The Tanning

The genuine British Oak Tanning Process gives McLaren's Belting that mighty toughness which makes them so lasting and reliable. No better method is known for treating leather for belts.

The Finished Belt

The use of McLaren's Belting reduces slipping to a minimum, thus saving considerable power. The lack of stretch reduces the amount of time, labor and attention required.
Let us send you a list of users. Then get their opinions.

THE ANDERSON

Model "D" Steam Trap

Allows No Escape of Live Steam

The valve is always locked with at least three inches of water, making the escape of live steam impossible.

A strainer and sediment chamber prevent sediment or scale from getting into the valve.

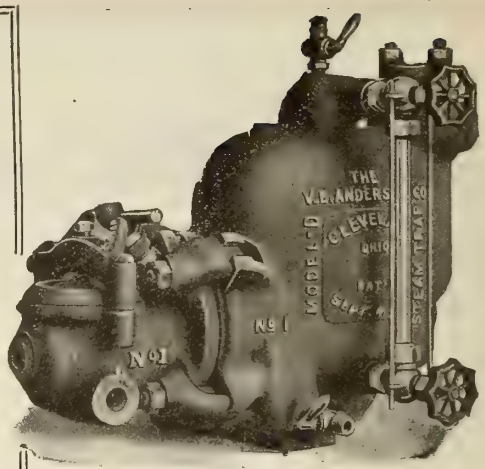
A glass water gauge, fitted to the valve, makes it possible to ascertain at a glance whether the trap is working properly.

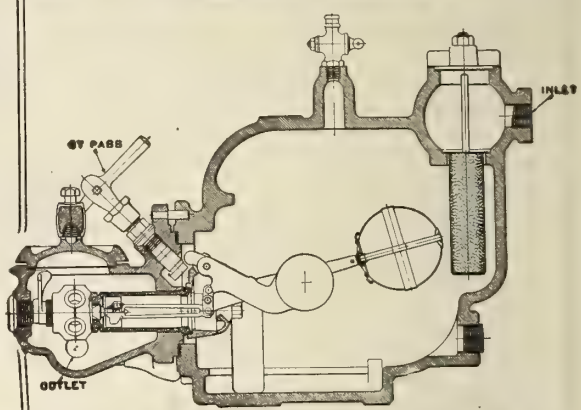
Both the valve and valve seat can be removed without breaking a steam joint or pipe connection.

The trap will lift water at any back pressure 5 pounds less than the pressure at the trap.

The Anderson Model "D" Steam Trap is accurate in every detail. Built of materials best suited for the purpose. Every part interchaneable.

Full particulars of these and other points will be forwarded immediately upon receipt of your request.





The V. D. Anderson & Company

1935 West 96th St., Cleveland, Ohio.

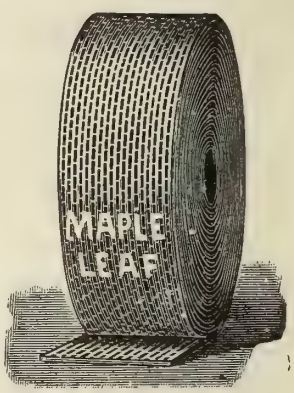
Dominion Belting Company, Limited

Hamilton, Canada

Sole Manufacturers of the celebrated "MAPLE LEAF" Brand Stitched Cotton Duck Belting and Belt Dressing.

The demand for our products has steadily increased because the standard of quality has been maintained.

We make only one grade, the best that can be produced.



"MAPLE LEAF" is the strongest, truest running, most economical and efficient belt on the market for transmission of power, conveying, etc.

Being thoroughly waterproof it is suitable for running in wet or dry places. **"MAPLE LEAF"** Belt Dressing is different to others offered in that it is equally good for all kinds of belting, leather, rubber or Balata, as well as our own make.

Write us for prices, and if desired we will be pleased to furnish samples and further information.

A trial order will convince you of their utility.

3—Open

Condit Oil Switch Construction

1. Note the perfect wiping contact of the Condit main laminated brush contacts, closed.

2. The circuit is broken by the auxiliary arcing tips. No arcing from main contacts.

3. Liberal Clearance when switch is fully opened.

4. Condit Type D-13 Oil Switch with individual Tank-per-Pole arrangement, providing high factor of safety.

¶ Condit D-13 Oil Switch has a maximum capacity of

300 amperes at.....27,000 volts
500 amperes at.....25,000 volts
and
800 amperes at.....15,000 volts

JENKINS
MARK

High Pressures Demand Exacting Service

The exacting service demanded of valves by high pressures cannot be met by merely additional all over weight.

Jenkins Extra Heavy Brass Globe Valves give exceptional satisfaction because of their extra weight of the **right** metal in the **right** places.

They hold absolutely steam, water, air and gas under high pressure for long periods without attention.

Every Jenkins Valve is made to withstand strains in excess of those which it will be called upon to endure in actual service. This is one reason why Jenkins valves are **dependable.**

The Jenkins line is so complete that—"There is a Jenkins Valve for every purpose."

Every genuine Jenkins Valve bears the diamond trade-mark—the sign of an iron-clad guarantee.

Catalog No. 8 upon request.

Jones Underfeed Stoker

Immediately Responds to Sudden Demands

Sudden demands for steam secure prompt action on the part of the stoker. The coal and fan automatically increase their speed the moment the steam pressure is reduced. Constant steam pressure is maintained even under fluctuating loads.

The Jones Underfeed Stoker eliminates smoke by stopping its formation, thus preserving the heating surfaces of the boiler free from soot.

Let us tell you the other remarkable advantages of the Jones Underfeed Stoker.

Get Clean Water for Your Condenser Intakes

by installing

Link-Belt Water Screens

LINK-BELT Traveling Water Screens automatically remove the debris from the water and insure a steady supply of clean water to the condensers at all times. They are self-cleaning, require little attention and can easily be adapted to almost any intake system.

Let our experienced engineers investigate your system and make recommendations. Write for catalog.

DEPARTMENT OF LABOUR
Ontario Government

Minister: Hon .W. R. Rollo

NOTICE TO STATIONARY AND HOISTING ENGINEERS AND STEAM PLANT OWNERS

Everyone operating a **Stationary** steam plant of 50 B.H.P. or over, and everyone operating a **Hoisting** steam plant working at a pressure of 20 pounds or over, irrespective of horsepower and used for hoisting in structural operations or excavating purposes, in the Province of Ontario, must hold a certificate from the Board of Stationary and Hoisting Engineers. Application forms will be forwarded upon request.

After January 1, 1920, all stationary steam plants in the Province of Ontario must be registered with the Board of Stationary and Hoisting Engineers. Application forms will be forwarded upon request.

All applications should be mailed to the Chairman of the Board. W. C. McGhie, Department of Labour, 15 Queen's Park, Toronto.

Deputy Minister: W. A. Riddell, Ph.D.

NOTICE TO MANUFACTURERS, DEALERS AND USERS OF STEAM BOILERS

All steam boilers built in, or entering, the Province of Ontario, and boilers exchanged or repaired, are subject to Government Inspection as prescribed in the Steam Boilers' Act, 3 George V., ch. 61.

Before any work of repair or alteration is commenced on any boiler, notice must be sent to the Department stating the nature and extent of the repairs or alterations proposed to be made. If the Chief Inspector should consider such repairs or alterations of an extensive character, the boiler must be inspected in accordance with the Regulations by an Inspector authorized under the Act.

All communications should be addressed to the Steam Boiler Branch, Department of Labour, 15 Queen's Park, Toronto. D. M. Medcalf, Chief Inspector of Steam Boilers.

ECONOMIC Carling BLOWERS SUPERIOR

Carling Turbo Blowers

For burning the lowest grades of coal successfully, getting all the heat value from the fuel. For positive draft with Automatic Control and steady steam pressure. For obtaining the ultimate capacity from the boiler.

Carling Blowers are low in first cost, easy to install and make a quick return on the investment. We will be pleased to show you why it pays to use Carling products.

Write to-day. Try at our expense.

MONCRIEFF'S

"UNIFIC" GAUGE GLASSES

The British Navy uses "Moncrieff's" "Unific". It is the kind that lasts.
It is a special feature of the "Unific" that it does not readily corrode; resists extreme changes of temperature and withstands the highest working steam pressure. In consequence it has a long life, justifies a higher price than the soda lime glasses, and is, indeed, the more economical purchase in the end.

Write for our catalogue.

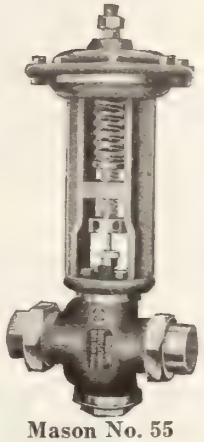
WHY "MASON"?

Mason Standard Bronze Reducing Valve

THE splendid reputation of the Mason Engineering Equipment is not the result of an accident, but the expected outcome of forty years of persistent effort backed by large capital and superior manufacturing facilities.

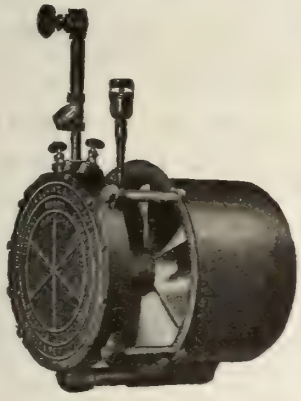
They hold the first place to-day because their merits entitle them to that position.

No other devices work so accurately, wear so long, nor accomplish their purpose so fully as the Mason. Once installed they are always demanded thereafter, and thousands of manufacturers absolutely depend on these devices working in many critical locations and find them satisfactory. This is where Mason Service comes in. We have at your service a staff of engineers, specialists in the application of our devices. Their job is to see that you do not throw money away on unsatisfactory equipment, and to help you to choose equipment that will do the work required.

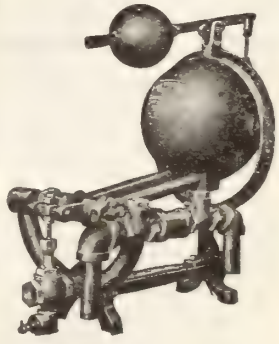


Mason No. 55 Pump Pressure Regulator

Coppus Turbine Driven Blower



New Bundy Return Steam Trap



We are very glad to hear from engineers who have a difficult problem in pressure regulation, engine or pump control, damper or blower regulation, or condensation drainage or returns. We have yet to hear of a problem, to which there is a possible solution, that we cannot solve.

HOMESTEAD
Quarter-Turn Valves

Homestead Valves will stay tight under any specified pressure up to 5000 lbs. Every valve unconditionally guaranteed. Try them on your lines—you take no risk.

Are Replacing Globes and Gates In Hundreds Of Plants

Here's Why

Only one quarter-turn is required to open a **Homestead** quarter-turn valve from absolute tightness **to a straight unobstructive flow,** while it takes anywhere from 6 to 10 turns of the wheel to open or close the ordinary globe or gate valve.

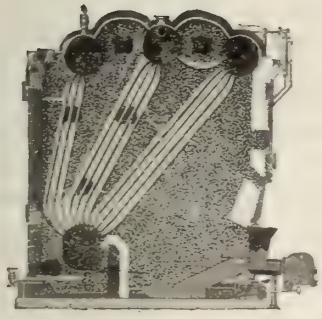
Homesteads are used for air, steam, water, oil or acids and will keep your pipe lines absolutely tight. **Order your requirements to-day.**

Catalog on Request

HOMESTEAD VALVE MFG. CO.
HOMESTEAD, PA.

Starrett Hack Saw Chart

THE L. S. STARRETT CO., ATHOL, MASS., U. S. A.
THE WORLD'S GREATEST TOOL AND HACK SAW MAKERS



Plastic Fire Brick in modern high stoker-fired furnace, including side and front walls, door arches, bridge wall and baffles.

Illustration shows Betson's Plastic Fire Brick Lining, including fire box, front wall of arch, furnace side walls, bridge wall, combustion chamber walls and rear arch.

Which Type of Boiler is Yours?

Regardless of type of Boiler or class of setting, when laid up of separate fire brick, furnace linings need frequent repair or replacement. This means overtime labor—perhaps a shutdown of the plant—at the best it is costly, annoying and repeated far too often.

BETSON'S
REG. U.S. TRADE MARK PLASTIC FIRE BRICK PAT. OFF.

is the ideal material for repairing and replacing furnace linings, and anyone can do the work.

Why not cut down this expense in your boiler room and increase the life of your boiler setting linings, baffles and arches, also reducing the infiltration of cold air?

Many keep a barrel or two of Betson's Plastic Fire Brick on hand at all times for emergency repairs.

Order to-day. Shipment will be made from our nearest branch or warehouse.

Write for pamphlet showing the way to use Betson's Plastic Fire Brick in your boiler room.

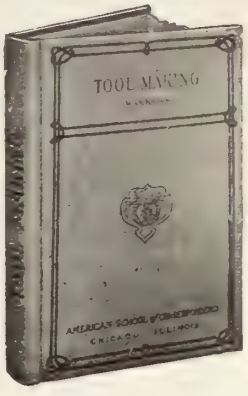
Clearance Sale of High Grade Technical Books



FOR several years we have maintained a Technical Book Department, handling high-class books published by various well known publishers. For various reasons we have now decided to discontinue our Book Dept. and in order to clear out what stock we have on hand we offer the following books at prices considerably lower than the regular selling price. Each item represents high quality at bargain prices. These books will not last long—first come first served. This is a fine opportunity to add to your technical library.

Title of Book.	Name of Author.	Binding	Number of pages	Illustrated	Price
Electric Chemistry	G. W. Cravens	Cloth	132	Yes	$1.10
Hawkins Electric Dictionary (Best)	N. Hawkins	Leather	537	No	2.50
Electricity Simplified	T. O. Sloane	Cloth	172	Yes	.85
Electrical Motor	E. E. Burns	Cloth	197	Yes	1.25
Starting a Printing Office	R. C. Mallet and W. H. Jackson	Cloth	90	Yes	1.45
Half Tone Process	J. Verfasser	Cloth	378	Yes	....
Modern Printing Machinery	Wilson & Gray	Cloth	455	Yes	4.50
Manufacture of Paper	R. W. Sindall	Cloth	275	Yes	1.50
System for a Medium Size Printing Shop	C. V. Simmons	Paper	26	Yes	.50
Embossing	R. H. Dippy	Paper	12	No	.25
Patents, Inventors, Advisers	Marion & Marion	Cloth	170	Yes	.75
Machinists' Guide	Wm. Rogers .	Cloth	323	Yes	1.50
Mechanical Refrigeration	S. Sydney .	Cloth	70	Yes	1.25
*Stationary Engineers.	Is in sets of three volumes.				
Boiler Construction	F. B. Kleinhans	Cloth	422	Yes	2.50
Audels Answers on Practical Engineering	Harris & Associates	Cloth	254	Yes	.75
Gas and Oil Engines	L. E. Brookes	Cloth	192	Yes	.85
Ford Car	V. W. Page	Cloth	288	Yes	....
New Catcehism of the Steam Engine	N. Hawkins	Cloth	429	Yes	1.50
Mechanical Arts Simplified	D. B. Dixon	Cloth	497	Yes	1.25
Setting Valves of Canadian-made Engines	G. C. Keith	Paper	31	Yes	.25
Change Gear Devices	O. E. Perrigo	Paper	81	Yes	1.25
Factory Power Costs	J. G. Branch	Paper	43	No	.75
The Field Engineer	Unable to find book in stock				1.50
Power Stations and Transmission	G. C. Shand	Cloth	84	Yes	.85
Liquid Air	T. O. Sloane	Cloth	365	Yes	2.10
New Guide Book to the Local Marine Board	C. M. Swainson	Cloth	545	Yes	1.30
Modern Machine Shop Tools	W. H. Van Dervoort	Cloth	552	Yes	3.00
Locomotive Catechism	R. Grimshaw	Cloth	432	Yes	1.50
Locomotive Breakdowns	G. L. Powers	Cloth	244	Yes	1.25
Modern Ironmonger		Cloth	341	Yes	1.00
Gas Engine Troubles	J. B. Rathbun	Cloth	448	Yes	1.00
Combustion of Coal and Prevention of Smoke	Wm. M. Barr	Cloth	347	Yes	1.25
How to Run Gasoline Engines	C. Von Culin	Paper	144	Yes	.50
Engineers' Library	W. H. Wakeman	Paper	Different No. in each	Some are	.25
Elements of Machine Design	J. H. Barr	Cloth	446	Yes	2.00
Hawkin's Indicator	N. Hawkins	Cloth	73	Yes	.75
Gas Engine Construction	Parcell & Weed	Cloth	304	Yes	2.00
Aids to Engineers Examinations	N. Hawkins	Cloth	222	No	1.50
Mechanism of Mechanical Movements	Unable to find book in stock				2.00
Pattern Making	Ritchey & Monroe	Leather	222	Yes	1.25
Machine Design	E. L. Wallace	Cloth	157	Yes	1.25
Foundry Work	B. L. Gray	Cloth	196	Yes	1.25
Forging	J. Jernberg	Cloth	131	Yes	1.25
Tool Making	E. R. Markham	Leather	288	Yes	2.00

***These books are in sets of 3 volumes to a set. There are eight sets in stock. The price of which are $4.50 per copy of $12.50 per set.**

Above prices includes postage. Cash must accompany order as at the reduced prices quoted accounts cannot be opened. Remit by express or P.O. money order or by registered letter.

The Safe and Certain Boiler Cleanser

PUT a barrel of BOICO in your boiler room. It's the most efficient and economical **clean-boiler insurance** you can adopt. BOICO routs the most stubborn cases of boiler scale formations quickly and thoroughly.

Hundreds of Plants are Using BOICO Every Day With Unqualified Success

What BOICO will do in one plant it will do in another—**it will do in yours.** BOICO loosens and brings away the hardest of old formations and keeps new scale from gathering. Yet it never does the slightest injury to boilers, valves or packings. Neither does it carry over in the steam, nor cause foaming or priming.

We are confident that BOICO will live up to all our claims and are prepared to let you test it FREE of cost. You have nothing to lose by trying it—let us hear from you.

Anti-Clinker Shell Bar Grates

There's no coal waste where these grates are used. Maximum air-space provides for perfect combustion. No clinker formation here, and you get more heat with less fuel.

One-Piece Jointless Furnace Lining

Why shift the blame on your engineer or fireman when it is your furnaces that are not up to the highest point of efficiency? USE PLIBRICO—it lasts longer than fire brick and is easier to instal.

Tip-It Patent Welding Process

With TIP-IT you get tools with shanks of carbon and tips of high-speed steel.

For Quality Equipment

POWER PLANTS

We specialize in the design and construction of power plant equipment. Our engineers are prepared to investigate your problems and advise on the most economical machinery for your needs.

We can supply Corliss, Slide-Valve, Vertical, Horizontal, Simple and Compound Engines, and Water tube, Return tubular, Improved Scotch Marine, and Portable Boilers.

Robb Equipment is known to engineers and power plant superintendents for its long and dependable service, standard quality and modern design. When you are in the market—remember it will pay you to purchase equipment that has won the confidence of leading engineers.

WM. B. SCAIFE & SONS CO. PITTSBURGH, PA.

Put a Farnsworth System to Work in Your Steam Plant

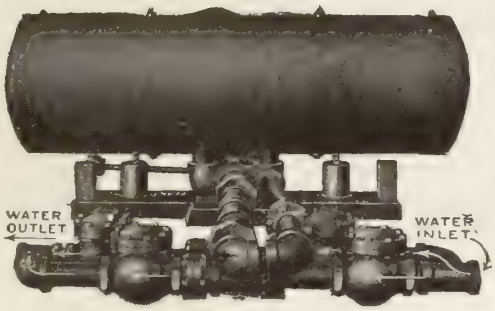
Farnsworth-equipped plants produce more steam with less fuel and less expense than other plants. Thousands of dollars are being saved by the Farnsworth System, not alone in Canada and United States, but in all countries of the world, wherever steam is used for heating or manufacturing process work—its value is thoroughly proven!

When the amount of expense saved by Farnsworth equipment is taken into consideration the question of installation costs is eliminated. It quickly pays for itself. It is a safe and profitable investment. Experience proves that in the majority of cases only three to six months' operation is required to return first costs.

These are facts. Plant owners have nothing to lose and everything to gain by investigating the Farnsworth System and the engineering staff of The Canadian Farnsworth Co. will be glad to advise and co-operate with them in solving steam line drainage and boiler feeding.

The Farnsworth Automatic Duplex Boiler Feeder

The "Farnsworth" should not be confused with ordinary steam traps. It is a machine built for Boiler Feeding. Note the cushioned dashpots, a feature which provides against shocks and ensures smooth operation.



The Sign of Coal Saving

No leaky steam valves with the Farnsworth in your plant; no constant waste of steam to the outside air; no springs to loose their tension; no levers to jump out of place; no weights to cause poundings, and no trunnions to bind and stick, or leak water and steam.

The Duplex feature of construction ensures a continuous flow of feed water to the boiler. Then, the machine being always equalized with the boiler provides against sudden shock or jar in the feed lines. There is no hold-up on the return lines as is the case with ordinary return traps, as the feeder is constantly receiving the water.

Our expert steam and condensation engineers are at your service. Have them investigate and make reports.

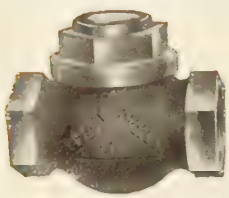
Your enquiries are solicited. Send for our Bulletins on Steam and Condensation — they are interesting and instructive.

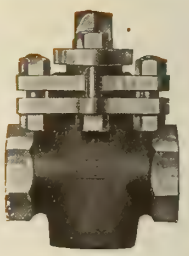
MORRISON

STEAM GOODS



J.M.T. Check Valve

UNVARYING IN QUALITY



Asbestos Packed Cock

The unvarying durability of Morrison Steam Specialties makes them safe and reliable. Before any article is allowed to leave the factory it is subjected to stress far in excess of that which it will be called upon to withstand in actual service.

The construction of the Morrison line represents the skill and knowledge obtained by over fifty years' varied experience.

Those familiar with Morrison products recommend them every time—they always make good. Approved by the Provincial Boiler Inspection Departments.

Strong where others are weak

PENBERTHY LEADERSHIP

in the making of "All Quality" Brass Valves is not a matter of chance

It is because of our ability to give to the engineering public a better valve at no greater cost.

The outside bonnet construction is the first radical improvement made in valve design for many generations past and is found in all valves bearing our trade-mark.

All Penberthy Valves Are Government Approved

TRADE PENBERTHY MARK.

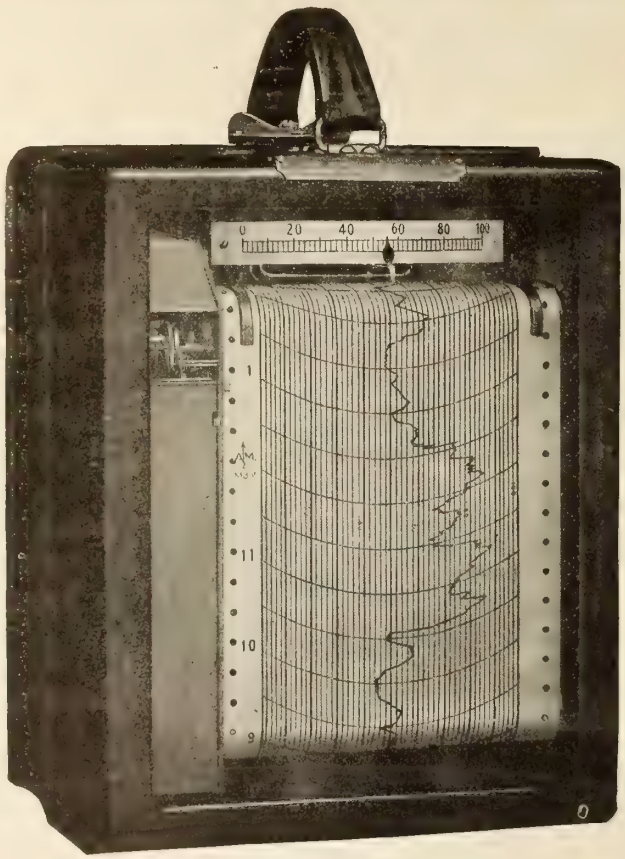
TRUE RECORDING INSTRUMENTS

Portable and Switchboard Types



Graphic Wattmeters **Graphic Voltmeters** **Graphic Power-Factor Meters**

¶ Ideal for generating stations, sub-stations, industrial and isolated plants where the value of a true load curve cannot be overestimated.

¶ The Illustration shows one of the Portable Graphic Meters, which is placed in an aluminum case with a glass face. The clock has an eight-day lever movement controlling the chart which is six inches in width and twenty-six feet long. A special inking device has been arranged for the marking of these charts. The holder will contain a supply for eight days and the ink is drawn through a tube to the pen by capillary action.

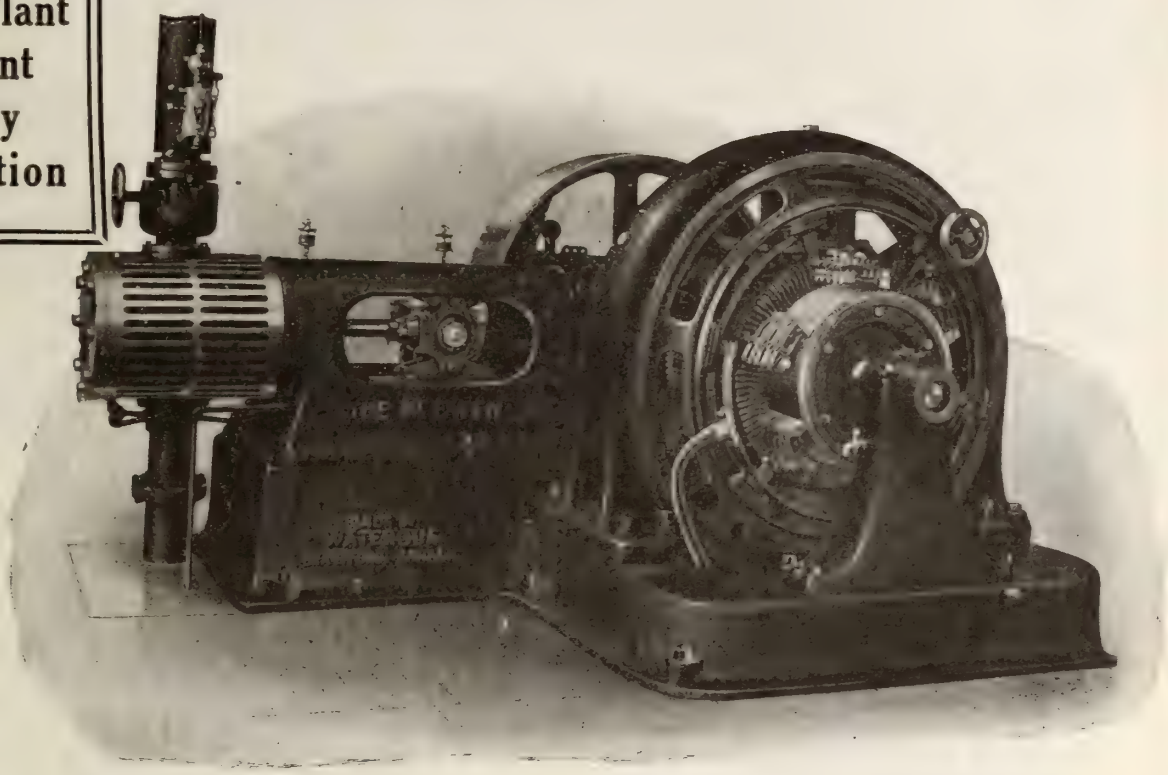
We Build Complete Power Plant Equipment for Every Installation



McEWEN HIGH-SPEED AUTOMATIC ENGINES

These dependable engines are built for continuous duty. They are your best insurance against costly repair bills and unexpected shut-downs.

They operate quietly and smoothly with an exceedingly close regulation under fluctuating loads. Sturdiness and their large reserve capacity enable them to respond instantly to heavy peak load demands.

Your careful investigation of their actual service performance record in all parts of the country specially requested. Let us send you our list of McEwen users.

Built in simple and compound units up to 700 H.P. capacity. May we send you descriptive literature?

Goodyear Belting keeps this cement mill at highest efficiency

Troublesome Small Pulleys

Have you trouble getting belts flexible enough for small pulleys, yet strong enough to last?

Goodyear has produced Extra Power Belting—belting flexible enough that it need not be too tight! Gripping enough to prevent slipping at any speed!

For this is 5-point belting.

1. It is extremely strong, because of specially-designed, properly-woven fabric.

2. Yet it is very flexible, for it is not stitched, but is welded together with high-grade rubber, forced through and through the fabric and surrounding every thread. It hugs even small pulleys.

3. It has a friction surface which *grips*, dry or damp, and needs no dressing.

4. It has a seam *sealed* tight with high quality rubber.

5. The same rubber which gives Goodyear Extra Power its flexibility, prevents ply separation, even when the edge is worn or torn by shifters or accident.

The list of satisfied users of Goodyear Extra Power Belting on small pulleys is very great—too long to print here. But a few are:

O'Neil Morkin Machinery Co., Edmonton, Alta.
MacEachern Milling Co., Wetaskiwin, Alta.
Silver Standard Mining Co., Ltd., New Hazelton, B.C.
Hollinger Consolidated Gold Mining Co., Timmins, Ont.
Tilbury Flour Mills, Tilbury, Ont.
Chisholm Milling Co., Toronto, Ont.
Essex Canning Co., Essex, Ont.
Border Cities Tool Co., Windsor, Ont.
Brechin Roller Flour Mills, Brechin, Ont.
Nipissing Mining Co., Cobalt, Ont.
St. George Pulp & Paper Co., St. George, N.B.
Ungar's Laundry & Dye Works, St. John, N.B.
Ganong Bros., St. Stephen, N.B.
Robb Engineering Works, Amherst, N.S.
Ed. Sinclair Lumber Co., Newcastle, N.S.
O'Brien, Limited, Nelson.
Dominion Pulp Co., Chatham.
Richard's Mfg. Co., Campbellton.

Any one of these firms will be glad to tell you of their experience with Extra Power. Or a Goodyear Belting man will call without obligation to you. Phone, wire, or write the nearest branch.

New Truths and Old Fallacies

Fusibility of Alloys—*Continued*

Binary alloys are classed as solid compounds, but in trinary and quaternary alloys only two of the elements are said to form a compound, as, for instance, in a tin-lead-antimony combination only the tin and antimony form the compound. Other characteristics in this connection will be discussed further on.

We give below the principal ingredients used in babbitt metals, and the approximate melting points, as we shall deal with these figures as we progress, viz.:

Tin, 446° Fahrenheit; Lead, 619° Fahrenheit; Antimony, 1166° Fahrenheit; Copper, 1992° Fahrenheit. It is axiomatic that good conditions will favor an inferior metal and adverse conditions militate against a good metal; hence it is not always possible to form an off-hand opinion as to the relative values of babbitts in actual service as careful comparative tests and records are generally necessary to reach a conclusion. In laboratory tests, however, comparative values can be determined quickly and acurately as maximum stresses can be applied and both water and oil lubrication used.

Genuine Babbitt was the first white metal alloy used for lining bearings and derived its name from isaac Babbitt, who first used it. He did not patent the mixture and was even uncertain as to its being the best, hence his patent merely covered the process of soldering alloy to the shell. However, his composition is about as good as can be made, and was used exclusively until lead base alloys appeared. Babbitt users naturally favored Genuine through force of habit and inherited custom and, therefore, when Magnolia was first introduced there was considerable opposition and mistrust regarding it.

To the man who doesn't care how it works, so long as it does the work

IF you are guided purely by precedent, when you select a steam trap, you will probably never know how good, how simple and how efficient a steam trap can be. Because there isn't a single thing about this 3-part Johns-Manville trap that in any way resembles the other kinds.

Four years ago the novelty of this trap appealed to everybody—now the efficiency of the trap itself has taken the place of its novelty features—because the trap brings results.

And now about results—The Johns-Manville Steam Trap discharges not only water of condensation, but air from any steam piping or apparatus, without the loss of steam. Size of pipe connections being equal, it has a greater capacity than any other trap of the same size that we have ever seen.

Year after year this trap has given and will give satisfaction to thousands of users to whom results are the only things that count.

Try out a Johns-Manville Steam Trap where you've been having trouble and watch it deliver the goods. Any of our branches will send the descriptive booklet and full information.

THE STOWE STOKER

EMPLOYING MECHANICAL DRAFT

Its fundamental principle is a conveyor feed, positive in action from coal-hopper to ash-pit.

What Makes A Coal "Free Burning?"

Recent developments in stoker and furnace design have made it possible to produce a free burning fuel bed from low volatile coals by preventing the primary caking and ultimate coking of the coal. When freed of this caking tendency each individual particle of coal retains its identity during its journey through the furnace, thus causing the burning bed to appear soft, white and intensely luminous. Eastern bituminous fuels are in every respect as free burning as western coals when burned on the Stowe Stoker.

1. The air openings of these stationary tuyeres are designed to introduce large quantities of air through the fuel bed during the early stages of combustion.

2. The severe incline of the grate subjects the fuel bed more directly to the intense heat radiated forward by this scientifically correct furnace arrangement.

These two influences destroy the binding properties of that material in coal which forms the primary coke structure, and in addition volatilize the tarry oils before the final coking can take place.

We also manufacture the L-C Chain Grate Stoker—the Natural-Draft Type for Higher Volatile Coals—Dominant in this Field Today.

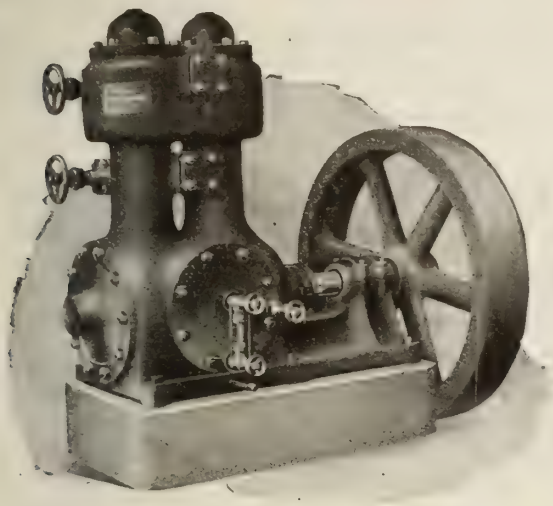
Mechanical Refrigeration



Reliable--Beneficial

THE many benefits common to all users of MECHANICAL REFRIGERATION, should make it a valuable adjunct to **your** business.

The uniform temperatures it provides have a better holding effect on the product in storage than ice, because the temperature produced by ice is not uniform, varying with the amount of ice in the refrigerator.

MECHANICAL REFRIGERATION permits the maintenance at all times of any temperature desired in the refrigerators or cold storage rooms, whereas you can not always get ice just when you need it, and a delay of a few hours often means a loss through deterioration of the product in storage.

If interested in MECHANICAL REFRIGERATION, a request for information and prices will receive our prompt attention.

An Investment—Not An Expense

TOO many users of refrigeration are apt to consider the insulation for cold pipes and tanks as an expense. And naturally the temptation is strong to cut first cost to the bone. Of course they are wrong, for good insulation—Nonpareil Cork Covering, for instance—is one of the most profitable investments they can make.

Under ordinary conditions Nonpareil Cork Covering saves 80% of the refrigeration that would be lost from bare, cold pipes and tanks. Generally speaking, that is enough to pay for its entire cost in the first twelve months. But it does not stop there. It is not an uncommon thing for Nonpareil Cork Covering to last ten years with ordinary care. In fact, it has records of twelve, fifteen and even twenty-two years of continuous service—paying a profitable return every year. The investment feature of Nonpareil Cork Covering appeals strongly to those who are using it. Doesn't it appeal to you?

The brine lines, ammonia lines, and brine coolers in the plant of the Sinclair Refining Company, Chicago, Ill., are insulated with Nonpareil Cork Covering.

If you are interested in a detailed description of the profit-paying possibilities of Nonpareil Cork Covering, you should have a copy of the 64-page illustrated book, "Nonpareil Cork Covering for Cold Pipes." Why not send for it to-day?

The Hot Process Boiler Feed Water Softener

A Short Treatise on the Effect of Heat on Chemical Reactions, and an Account of Some Experiments Carried Out by the Harrison Safety Boiler Works

THE hot process softener in its present form is a recent development. By taking advantage of the fact that chemical reactions are more rapid and complete in hot water than in cold water, more efficient removal of scale and sludge-forming substances obtained. The apparatus performs the functions of the open feed-water heater usually found in steam boiler plants, in addition to those of a softener, and less space, lighter foundations, less housing, less piping and fewer fittings are required than for a cold process softener plus an independent heater. There are several reasons why scale-forming matter is more completely removed from hot water than from cold water.

Effect of Heat Upon Reactions. — Chemical reactions are enormousy accelerated by heat. This is a well-known and generally recognized fact, and was used in the household for ages before it assumed the dignity of a law of chemistry. Everyone knows that dishes and clothes are washed more rapidly and thoroughly in hot water than in cold water. Paper pulp is causticized in hot water, etc., etc. The exact law connecting temperature and rapidity of chemical reaction has never been determined accurately, some chemists stating that the speed of reaction doubles for each ten deg. C. added to the temperature, and others that chemical reactions are speeded up approximately as the twentieth power of the absolute temperature. These formulas are not in agreement, but everyone concedes that there is a tremendous increase in speed of reaction with rise in temperature.

Some years ago experiments were made in the chemical laboratory of the Harrison Safety Boiler Works to determine the effect of temperature upon the reactions which take place between softening reagents and scale-forming matter in boiler feed water. The results are shown graphically in Fig. 1.

It will be seen that the reduction in hardness, that is, in content of calcium and magnesium salts, is much greater at the end of ten minutes in water at 210 deg. F. than at the end of five hours in water at 50 deg. F., in fact twenty-four hours treatment in cold water does not bring the scale-forming matter down as much as does ten minutes' treatment in hot water. Subsequent heating to the boiling point of the sample, which has stood at 50 deg. F. for five hours reduces the magnesium hydrate to less than 1 grain per gallon, but the same result is obtained in hot water in 10 minutes. In performing these experiments, only sufficient softening chemical was added to combine with the scale-forming substance. In practice a slight excess is used, which reduces the hardness to lower figures.

The effects of heat can be verified in a rough way by performing the experiment shown in Figs. 2, and 4.

Place one pint of cold, untreated boiler feed water in each of two breakers, bring one of them up to the boiling point, but leave the other cold. Then add to each the amount of reagent theoretically required for transforming the scale-forming substances.

Stir thoroughly the contents of each beaker and note results. The reaction and sedimentation in the hot water will be much more prompt than in the cold water.

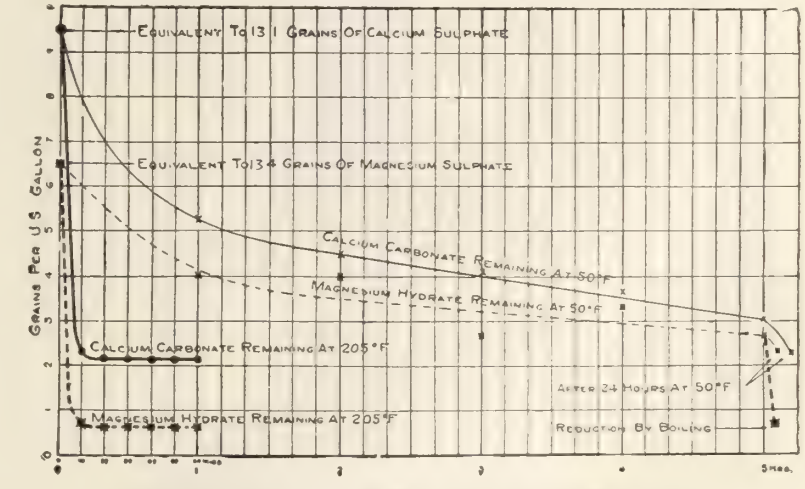
After precipitation has ceased in the cold water, decant the clear liquid and heat it to the boiling point. A marked after-precipitation will result, showing that the reaction in cold water was not complete. Do the same with the clear water from the hot water beaker. No after-precipitation will occur, so it is conclusively shown that the reaction is not only more rapid in the hot water, but is also more complete.

The substances resulting from the transformation of scale-forming matter are more nearly insoluble in alkaline hot water than in cold water, hence less are carried into the boilers in solution by water which has been softened hot.

Effect of Heat Upon Sedimentation.— The precipitates resulting from the transformation of scale-forming substances also settled more rapidly and completely from hot water than from cold water. Solid particles suspended in water settle to the bottom if their density is greater than that of the water or rise to the top if their density is less than that of the water. The force acting upon the particles is its weight less the weight of water displaced, and the force by which it is resisted depends upon the extent of its surface and the viscosity of the fluid in which the particle is suspended, multiplied by the velocity of fall. A maximum velocity is reached at which the retarding force is just equal to the accelerating force.

Viscosity is the resistance which a fluid offers to shearing. The co-efficient of viscosity may be defined as equal to the tangential force required to slide a unit surface at unit velocity at unit distance from another surface with the fluid between.

Obviously, a large particle will settle



SHOWING EFFECT OF TEMPERATURE ON PRECIPITATION.

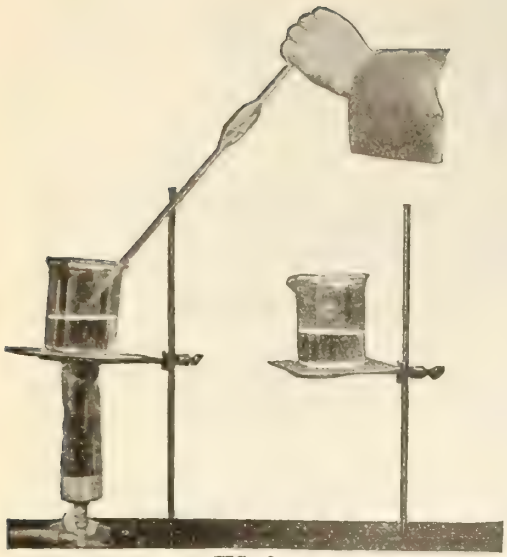


FIG. 2.

more rapidly than a small particle, because it contains a greater mass, and hence is acted upon by a greater force, in proportion to its surface. Considering a spherical particle, whose density is greater than that of water, the maximum velocity with which it falls is given by Stokes' formula:

$$V = \frac{2}{9}\,\frac{D-d}{N}\,gr^2,$$

in which V is the velocity, D the density of the particle, d the density of the water, g the acceleration of gravity, r the radius of the particle, and N the co-efficient of viscosity.

In a water softener the precipitated particles are of various sizes, and possibly of different densities, but any given particle will fall through the water at a rate depending upon the viscosity, and it is therefore of interest to note how the viscosity of water changes with temperature, as shown in the following table by Thorpe and Rodger:

Temperature Degrees F.	Coefficient of Viscosity
32	.01778
50	.01303
68	.01002
86	.00798
104	.00654
122	.00548
140	.00468
158	.00406
176	.00356
194	.00316
212	.00283

At the freezing point the viscosity of

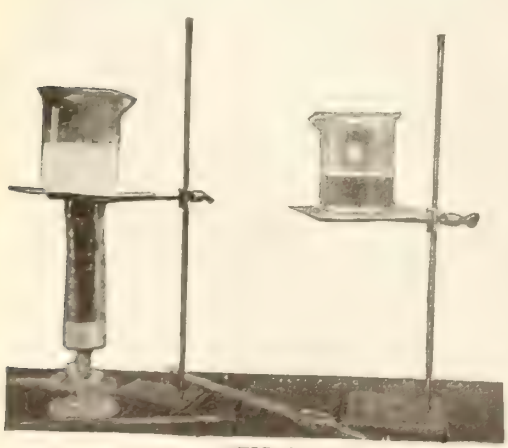

FIG. 3

water is over six times as great as at the boiling point, while as between water at 68 deg. F. and water at 212 deg. F., the increase in velocity of fall will be about four times.

Now, consider how this applies in a water softener. Suppose we have a large tank full of absolutely quiet water. A particle of any given size will descend four times as far as in an hour in hot water as it will in cold water.

Next, suppose we have a continuous softener in which the water is constantly flowing through the sedimentation tank. The rate of flow can be four times as great in a hot-process softener as in a cold process softener, without carrying particles of a given size to the pump supply pipe, or to put it in still another way, with a given rate of flow through the settling chamber much smaller particles can be separated out in the hot-process softener than in the cold-process softener. The further fact that the particles formed in a hot-process softener are larger than those formed in a cold-process softener renders the advantage of the hot process still greater, since the velocity of fall increases as the square of the radius of the particle.

It is therefore plain why the preliminary heating of the water, a feature which is peculiar to the hot-process softener, gives more complete chemical reactions and more thorough removal of the resulting precipitates.

The completeness with which scale-forming matter is removed from water treated in a hot-process softener may be shown by the following analyses of water before and after treatment in a commercial installation. In considering these results, it should be borne in mind that a grain is 2-7000 of a pound, or 1-58,415 of the weight of a gallon of water. The small amount of solida remaining in the treated water from a hot-process softener does not form scale in the boiler, but gathers as sludge, which is easily blown out.

	Before Softening	After Softening
Calcium sulphate	13.00	none
Calcium carbonate	12.30	.36
Magnesium carbonate	5.36	.94
Silica	.82	.35
Iron and aluminum oxides	trace	trace
Total increasing solids.	31.48	1.65
Organic and volatile	6.32	2.98
Sodium carbonate	...	4.80
Sodium sulphate	.64	12.60
Sodium chloride	2.28	1.92
Total non-incrusting solids	9.24	22.30
Free carbonic acid	2.45	

The chemical reagents must be fed to a softener accurately in proportion to the amount of water and to the impurities in the water, so that the treated water may not deposit scale on the one hand or contain an excess of unused reagents on the other. For proportioning the reagents to the raw water supply various mechanical arrangements have been devised.

In some softeners, the raw water flowing to the softener turns a water wheel or operates a tilting bucket, whcih, in turn, operates dippers by which the reagents are ladled out to be mixed with the raw water.

Such appliances, widely used with cold-process softeners, are usually located above the reaction chamber of the softener, involving the lifting or hoisting of the reagents 15 or 20 feet or more above the ground level.

In other softeners, a certain portion of the water, divided from the main supply by means of orifices or weirs, flows through chambers containing the reagents. In one such proportioner, the water in flowing through the reagent tank becomes saturated. This method is faulty, however, since solubility varies greatly with temperature.

In another form the water displaces the reagent from a tank, at the same time diluting that which remains in the tank. Elaborate means for adjusting the orifices progressively as the reagents become more and more dilute are therefore required.

None of these methods is well adapted for feeding chemicals to a hot-process softener, which should be designed for operation under a few pounds' back pressure, since it is necessary to carry a few pounds' back pressure upon the

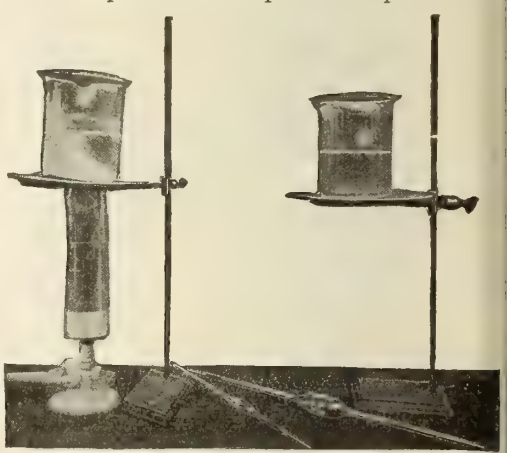

FIG. 4

exhaust steam, in order to insure a temperature of at least 205 deg. F. of the treated water at all times. With the methods just mentioned, it is necessary that the chemical feeding equipment be enclosed within the steam space, or else that the chemical and raw water, after being proportioned, be pumped into the softener against the back pressure. If the water wheel, or the tilting bucket, is enclosed so that the reagents can flow by gravity directly to the reaction chamber, steam finds its way into the chemical tank, where it condenses, diluting the reagents and rendering the feed inaccurate. The dividend flow method involves an additional pumping of both the raw water and the reagent, and is therefore complicated and expensive.

In still another arrangement the raw water is passed through a hydraulic motor, of the reciprocating or of the rotary form, which drives a small chemical pump. This method is defective because it is practically impossible to prevent slippage past the valves and pack-

ings of such motors and pumps, which renders the proportioning inaccurate.

The chemical proportioner used in the Sorge Cochrane hot-process softener to regulate the feed of chemicals in proportion to the flow of raw water is a true flow proportioner. The chemical to be fed to the softener is forced through an orifice by a pressure just equal to the differential pressure set up by the flow of the raw water through an orifice in the supply pipe.

To understand how the device works, refer to Fig. 5. Between two flanges in the pipe through which the raw water softener is placed a thin orifice disk.

From the two sides of the orifice, small pipes lead to the opposite ends of a cylinder containing a piston. The piston is thus acted upon by the differential pressure due to the flow of water through the orifice.

The vertical piston rod extends through water glands at each end of the cylinder. On the lower end of the rod is a valve disk, which closes over an opening, through which a fluid mixture of the reagents is constantly being forced by a centrifugal circulating pump. The weight of the piston, rod and valve disk is counterbalanced.

The differential pressure acting upon the piston pushes the disk down upon and tends to close the opening, while a pressure builds up underneath just sufficient to balance the differential pressure. The pressure of the chemical solution is therefore directly controlled by the differential pressure resulting from the flow of fater through the orifices in the raw water pipe. Through a simple pipe connection, this pressure acts directly at the chemical orifice, insuring an effective pressure on this orifice at all times equal to the differential pressure on the raw-water orifice. Most of the chemical solution supplied by the circulating pump flows out from under the disk and through a strainer, and hence back into the chemical solution tank. The proportioned chemical flows through the chemical orifice into a funnel, from which it is taken by a chemical feed pump, lifted to the softener and forced in against any back pressure that may exist in the latter. The back pressure in the softener thus does not affect the proportioning.

As the chemical, before escaping through the small orifice, is not in contact with air, no incrustation occurs therein, but to provide for dislodging any obstruction, a cleaning needle is so arranged that it can at any time be forced through the orifice by the pressure of the hand.

Besides being accurate, this arrangement has other advantages:

Only one chemical solution tank is required, which is at the ground level, where it can be charged without hoisting of chemicals or inspected without climbing a ladder.

The motor which drives the circulating pump also drives agitating paddles in the tank. Milk of lime can thus be kept in suspension and fed as well as purely fluid reagents. The large saturator tanks necessary where lime water is used are eliminated and the difficulty, due to the fact that lime water varies in strength according to temperature, is avoided.

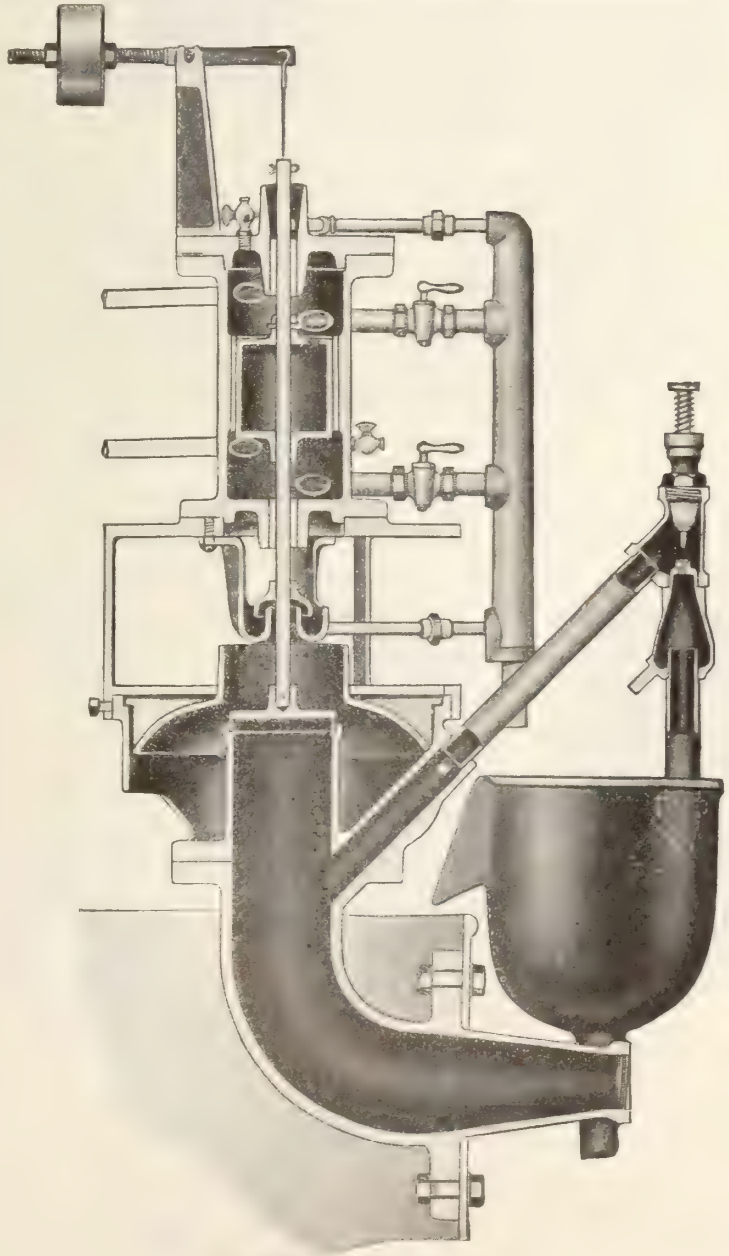
Solutions of caustic soda or sodium carbonate, lime water, milk of lime, or any mixture, are all handled equally well and fed accurately.

The accuracy with which the solution is fed is well within 2 per cent., which is closer than attendants will measure out chemicals into the chemical tank Representatives test results are shown in the following table:

Rate of Flow of Raw Water Gals. Per House	Rate of Flow of Chemical Gals. Per Hour	Chemical For Gallon of Water	Variation Per Cent.
1740	134.6	.0773	0.28
1590	122.2	.0769	0.22
1410	86.8	.0769	0.22
1160	86.6	.0769	0.71
710	54.6	.0769	0.22
411	31.8	.0773	0.28
290	22.4	.0775	0.52
164	14.3	.0771	0.03

The chemical treatment is controlled by drawing a sample of the treated water from time to time and titrating with standardized solutions, the whole operation requiring about ten minutes. By locating the titration readings thus obtained upon a chart for correct chemical treatment, the operator sees at a glance what change, if any, is required in the amounts of the chemicals.

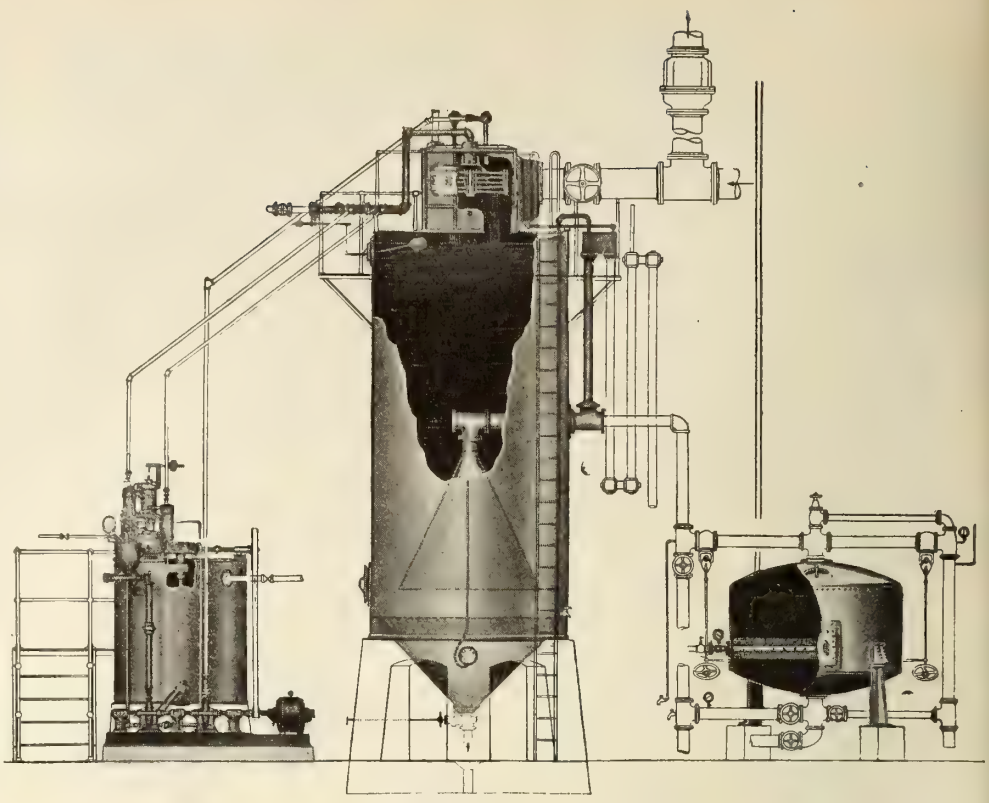
The Sorge-Cochrane hot process apparatus, as may be seen in Fig. 6, is simple and compact. The open heater, with an oil separator attached for purifying the exhaust steam used for heating the water, is mounted directly over the reaction and sedimentation chamber.



CHEMICAL PROPORTIONER.

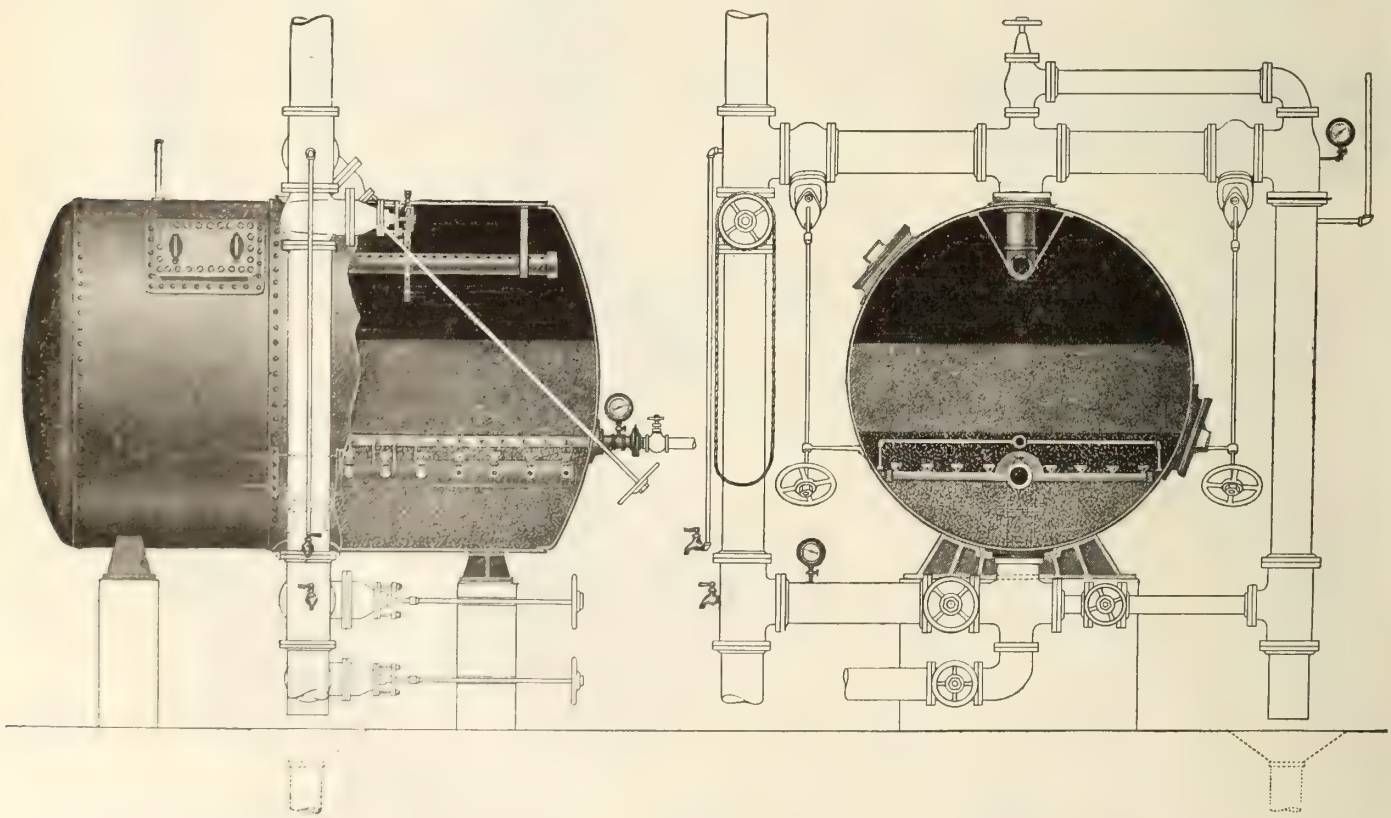
The water is heated to steam temperature by spraying it over trays, which also serves to release oxygen and other disolved gases. It is then mixed with the reagent and falls directly into the sedimentation tank. There is no constricted piping between heater and tank to become chocked with scale. In fact, the water does not pass through piping from the time when it is first heated until it has been through the sedimentation chamber, even the overflow receiving only settled water.

The precipitated matter deposits in the conical bottom of the sedimentation chamber, from which it can be quickly washed by the opening of a single valve. In order to eliminate convection currents the hot water and the softening reagents are delivered at the top, and travel slowly to the bottom, from which the clarified water is drawn off by an inverted funnel. The precipitates formed when the water is first mixed with the chemical fall through the water below, securing a screening effect and gathering together the smaller particles. All precipitates are carried to the conical bottom of the tank, from which they are readily blown out by opening a sludge valve at the lower end or apex of the cone.



HEATER ARRANGEMENT.

Filters.—The removal of scale-forming matter at high temperature by sedimentation is so effective that for many waters and plant conditions it is entirely practicable to dispense with filters. Many softeners are accordingly installed without filters and are successfully protecting the boilers from scale and corrosion, even though the softened water contains a slight amount of suspended matter. Other conditions demand the use of filters, for which a low-pressure sand filter is placed between the sedimentation tank and the boiler feed pumps or meter, the water flowing through the filter by gravity. These filters deliver a crystal-clear water, which contains no solids except those in solution, and no mud-forming properties except the amount which is below the exceedingly low limit of solubility of calcium and magnesium monocarbonates, silica, etc., at the boiling point. This water will leave no troublesome deposits in the feed lines, pumps or meters, and



FILTER TANKS.

is particularly suitable for boilers operated at high ratings.

The filter is essentially a bed of fine sand resting upon a bed of gravel. Embedded in the gravel layer are strainer heads or valves. The strainer valves are of a self-cleaning type, having a movable head or disk, which rests upon the stationary part of the valve in such a way as to leave small openings or ports around the edge. In back washing, the water is admitted through the strainers in a reverse direction and lifts the disks or heads, increasing the openings of the ports to double the normal size, with the result that any particles of sand or other substances which may have lodged in the port during the filtering operation are released and carried out by the wash water.

The strainers may be screwed into a collecting and wash water distributing manifold, as illustrated in Fig. 7, or into a diaphragm.

Embedded in the gravel layer is an air dstribution system consisting of a main pipe with laterals, the latter perforated on the underside to permit the escape of air throughout the gravel layer. The air is used for loosening up the filter bed preliminary to back washing, the proper rate of air admission being controlled by an orifice in the pipe connection.

The filter chamber is connected to the softener through valves at the top or inlet and to the boiler feed pump from the bottom or outlet chamber. There is also a valved by-pass from the softener directly to the boiler feed pump suction. The inlet and outlet of the filter are connected through hand-operated gate valves to a waste pipe, to which a relief valve at the inlet also discharges. Finally, there is a connection to the outlet opening from a water supply, for back washing. A pressure gauge is provided to show when the filter needs washing. Back washing is done at intervals, several times daily, the frequency depending upon the character of water. In some installations, more than one filter is installed, so that it is not necessary to feed unfiltered water to the boilers while washing.

SHEFFIELD WIRE ROPE

Sheffield is justly proud of its wire ropes, for it makes the steel as well as the ropes, and Sheffield steel being the best it naturally follows that Sheffield ropes are the best, whether for ships' rigging or for mining haulage purposes. Wire ropes were first made in Sheffield in 1860. First there was a considerable demand for these ropes from colliery companies, then from the big works in the district, and next from the shipping fraternity. Besides the local demand for colliery haulage ropes, for ropes for the heavy steel and engineering works, and for shipping, there was very soon a big trade in wire ropes for various foreign countries and the colonies, especially for the gold mines. But the biggest demand has been, of course, on shipping account. Both naval and mercantile ships very speedily became users of wire ropes, and Sheffield has done a big trade in this line for two generations. All classes of wire ropes are made in Sheffield. The original works have been greatly extended, and fresh works, established in 1887 and in 1910. These have, in turn, also been extended quite recently. More than 6,000 tons of wire ropes are now turned out annually. There are dozens of different qualities or classes and gauges. There are ropes for rigging, for lifting, for haulage, for aerial or overhead railways, flexible ropes for drums and pulleys, and ponderous ropes for mining equipment, each and every kind made from some special steel to suit the purpose. The wire these various ropes are made from is all of high strain quality—80 to 120 tons per square inch—and the greatest care is taken in the processes of manufacture to produce the necessary uniform hardness, toughness and flexibility, according to the work for which the ropes are designed.. To avoid brittleness and to withstand the abrasion on pulleys, for instance, special steel is produced, and both the wire and the ropes are put through special processes. Everything in this group of products, from ropes weighing many tons to the finest wire for pianos, is made in Sheffield, from Sheffield steels, and by workmen who are artists in their line. Only a few months ago Sheffield sent out a rope five miles long, and 21 tons in weight, whilst much longer, but not heavier, ropes have been made from time to time. At the present moment a machine is being completed in the city which will spin and carry ropes up to 30 tons in weight. Every imaginable requirement of the navy, the mercantile marine, and of mining is being anticipated by Sheffield wire rope makers. There are three big wire rope-making plants in the city. The Sheffield Wire Rope Company, Ltd., is established at Darnell, within the city boundary, and produces every kind of rope required for shipping, mining, crane and engineering purposes. Messrs. John Shaw, Ltd., of the Yorkshire Wire Rope Works, Sheffield, supply the same classes, and besides having a big British shipping connection they make a special point of colonial requirements, and have branches in Melbourne, Adelaide, Perth, Kalgoorlie, Auckland, Johannesburg, and Bulawayo Messrs. Wm. Cooke & Co., Ltd., of the Tinsley Wire Rope Works, Sheffield, particularly specialize in the heavy varieties of rope, and do a big and growing trade in shipping, trawling, engineering and mining ropes.—"Syren and Shipping."

In a recently issued Bulletin of the United States Geological Survey some information was given on the subject deep wells and shafts. This Bulletin, according to the South African Mining and Engineering Journal, is incorrect in regard to the depth of shafts. It says that the deepest mine in the world is shaft No. 3 of the Tamarack Mine in Houghton County, Michigan, which has reached a depth of 5200 ft. The Bulletin, it is presumed, refers to metalliferous mines only. If this be so, then the deepest mine in the world is the Turf shaft of the Village Deep, Limited. The vertical portion of this shaft intersects the reef at 4300 ft. and on the continuation of the blanket beds the incline has been sunk an additional 3000 ft. The vertical depth from the surface to bottom of the incline is now 5861 ft., so that the Village Deep Turf shaft is more than 600 ft. deeper than the No. 3 of the Tamarack Mine. The Turf shaft is now, in fact, down to sea level.

Particulars were recently given in the Bulletin of the Federation of British Industries of Finland's potential water power resources. Out of a total estimated water power of 3,000,000 horsepower at average water level it is considered that about 1,050,000 horse-power could be of direct use for industry. Of this only 150,000 horse-power is at present utilised, thus leaving considerable possibilities of development. Of the 79 waterfalls in Finland with potential capacities of horse-powers from 5000 to 300,000, 42 range from 5000 to 20,000 horse-power, 25 from 20,000 to 50,000 horse-power, 6 from 50,000 to 100,000 horse-power, and 6 from 100,000 horse-power to 300,000 horse-power.

Experience has shown that wire ropes of compound construction, subjected to corroding influences, are likely to deceive engineers as to the strength remaining in them, says a circular issued to managers of mines on the Rand, South Africa. Where reduction of diameter or circumference of the rope has taken place, not accounted for by the evidence of wear, the part of the rope under examination should first be fully loaded and then relieved of the load. Any noticeable difference in circumference in these circumstances and slackeneing of the outside wires when the load is off will indicate that internal corrosion has taken place. The extent of corrosion inside the strand can only be estimated by the slackness of the outside wires. The corrosion between the strands can be further examined by untwisting the rope or displaying the strands sufficiently with a marlin spike.

A new form of black japan, in which a non-combustible solvent is employed, has recently been brought out in America. The material, is, in fact, an emulsion of the asphalt oil base with water. It is stated that this japan has no tendency to settle out, even after months of storage, and that, owing to its being suspended in water, losses by evaporation are practically negligible. The japan is applied to small articles by placing them, charged positively, in a negatively charged iron tank of japan. An even, smooth coating of japan is deposited on the articles, and since the japan is deposited free from solvent, there is no resultant drip when the lot is conveyed to the baking ovens. In the case of large articles the metal is pre-heated before dipping.

A Description of the Busch Sulzer Diesel Engine

At a Time When the Internal Combustion is Assuming Such an Important Position in the Engineering World, This Article Describing the Principle and Operation of a Well-Known Type Should be of Interest

THE DIESEL ENGINE is an internal combustion engine which utilizes, directly in its cylinder, any heavy liquid fuel, ranging from kerosene to coal tar.

It requires neither carburetors nor ignition systems.

Pure air, with which the engine cylinder is filled, is compressed by the upwards-travelling piston to a pressure of 450 to 500 pounds. Its temperature increases, due to this compression, to approximately 1000 degrees Fahrenheit. At or near the upper dead-centre of the piston, the fuel is sprayed into the cylinder, gradually and in a finely nebulized condition. The fuel is gasified and ignited by the heat of the compressed air, without any supplementary means; it burns during the first part of the piston down-stroke, after which the hot gases in the cylinder continue to expand and perform work on the piston, until they are exhausted from the cylinder.

The rate at which the fuel is injected into the cylinder is so adjusted that its ignition and combustion take place without explosive violence, and with substantially no change of pressure; for which reason this type of engine is sometimes referred to as the "constant pressure" type, to distinguish it from the "constant volume" type, such as gas, gasoline, and hot bulb oil engines, and engines improperly designated "semi-Diesel," in which the combustion takes place substantially without increase in volume, and therefore with an explosion-like increase in pressure.

Diesel engines are built to operate on either the four-stroke cycle (briefly, "four-cycle"), or the two-stroke cycle (briefly, "two-cycle") system.

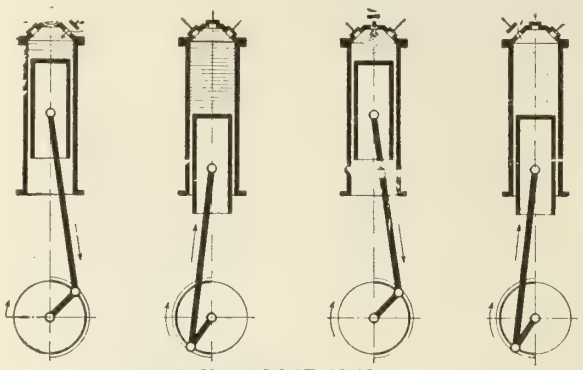
This article describes an American made Diesel Engine operating on the four-stroke cycle, a four cylinder vertical enclosed crank case Diesel Engine known as the "Busch-Sulzer-Diesel" and manufactured by the Busch-Sulzer Bros. Diesel Engine Co., St. Louis, Mo., U.S.A. In a four-cycle engine, four strokes of the piston, or two revolutions of the crankshaft, are required to complete the cycle of operations. These operations are illustrated in Figures 1 (a) to (d), each of which is accompanied by a description.

(a) First stroke: (admission stroke); piston travels down; admission valve open; cylinder is being filled with pure air.

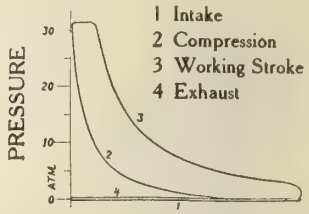
(b) Second stroke: (compression stroke); piston travels up; all valves closed; air in cylinder is being compressed.

(c) Third stroke: power stroke; piston travels down; fuel valve open at top dead center, but closed at fraction of stroke; gases expand.

(d) Fourth stroke: (exhaust stroke); piston travels up; exhaust valve open; burnt gases are being expelled from cylinder.



THE FOUR-STROKE CYCLE.
1st Stroke—Admission Stroke.
2nd stroke—Compression Stroke.
3rd Stroke—Power Stroke.
4th Stroke -Exhaust Stroke.



TYPICAL INDICATOR CARD

Figure 2 shows a typical indicator diagram from a four-cycle Diesel engine, on which diagram the lines representing the various operations are lettered to agree with Figues 1.

The fuels used in Diesel engines are crude petroleum and the heavier petroleum distillates or fuel oils. Kerosene and tar oils are but rarely used in this country for this purpose, because their relative cost is higher and their practical efficiency lower.

Efficiency

There is no other known method of generating power from fuel which can approach the Diesel in efficiency. By efficiency is here meant the proportion of the energy contained in the fuel which is transformed into useful energy; this is most readily compared on the basis of heat units.

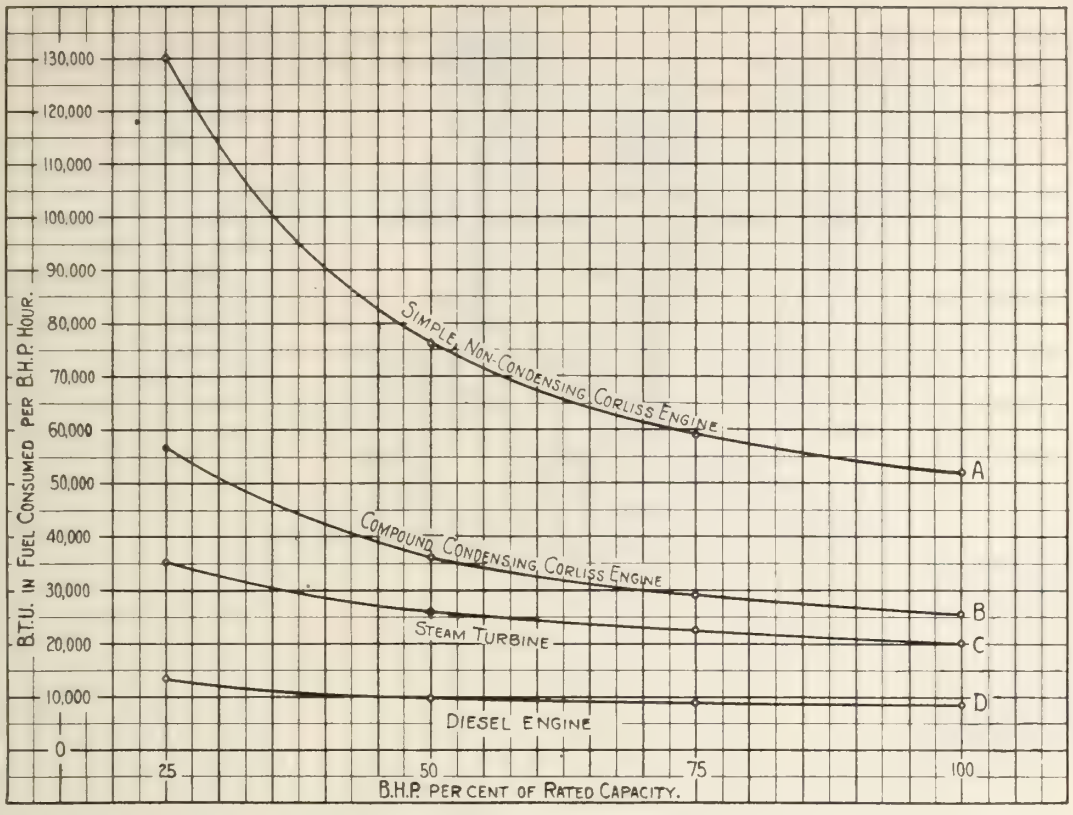
Bituminous coal, as ordinarily used for firing under steam boilers, contains 10,500 to 14,500 heat units per pound. The average is somewhat below 12,500.

Fuel oil, as used for firing under steam boilers and for combusion in Diesel engines, contains 18,000 to 19,500 heat units per pound. The average is about 18,800 heat units per pound, or 143,000 per U.S. gallon.

To compare the efficiencies of various prime movers, cognizance must be taken of the average power developed, and the normal operating conditions. Steam plants are subject to losses in the boilers, due to radiation and leakage; as also steam consumption by auxiliary apparatus, such as feed pumps and condenser pumps. The heat consumed by these does not decrease in proportion to the reduction in the power developed. Added to this, most steam plants must keep up steam during periods when the prime movers are not running; and steam in excess of the immediate requirements, during portions of the running periods;—these "stand-by" fuel consumptions will vary from zero in an ideal plant operating continuously at a constant load, to 25 to 30 per cent. of the useful consumption in a plant operating intermittetly or with variable load.

In the appended table are shown the heat units (B.T.U.) contained in the fuel consumed in plants of several types, per useful horsepower (B.H.P.) per hour, when the prime mover is operating at constant loads, for full-rated and fractional loads, and without any allowance for stand-by combustion. In the headings are stated the sizes of the units, their operating conditions, and the full-load steam consumption of the prime mover only. The heat consumption in all cases, include the auxiliaries and are based upon good ordinary operation as distinguished from test conditions. To obtain the pounds of coal, equivalent to the heat consumption, divide by 12,500; or to obtain the gallons of fuel oil, divide by 143,000. For example: at a constant load of 50 per cent. of its rated capacity the 400 I.H.P. compound condensing Corliss engine plant consumes 29,000 B.T.U. per B.H.P. per hour, which is equivalent to 2.32 pounds of coal, or 0.203 gallons of fuel oil; while the Diesel consumes 9,800 B.T.U., equivalent to 0.069 gallons of fuel oil. The steam plant, will, in addition, rarely consume less than 10 per cent. for stand-by; whereas the Diesel plant has no stand-by consumption. The actual comparison would thus be 0.069 gallons, or about 3 1-4 to 1 in favor of the Diesel.

When referring the tabulated heat or the resulting fuel consumptions to elec-



CURVES OF COMPARATIVE FUEL CONSUMPTION.

tric power, the actual consumptions must be corrected to allow for the losses in the generator; but the relation between the consumption will remain substantially unaffected. For example: At 50 per cent. of the prime mover power, the generator would have an efficiency of about 90 per cent., and the fuel consumptions per K.W. Hour, of the two plants above referred to would be equivalent to the fuel consumption per B.H.P. per hour, multiplied by 1.34 and divided by 0.90; i.e., 0.33 gallons of fuel oil per K.W. hour for the steam, and 0.102 gallons for the Diesel; (this would be equivalent to a consumption of 3.8 pounds of coal per K.W. hour, for the steam plant).

The curves in Figure 3 show graphically the average consumption of heat units in fuel, in ordinary land power plants, A being a simple non-condensing Corliss engine plant; B, a compound, condensing Corliss engine plant; C, a steam turbine plant; and D, a Diesel engine plant. Note the very flat curve of the Diesel, showing the maintenance of high efficiency throughout its load range, which is characteristic of this type of prime mover.

In all of the foregoing comparisons it has been assumed that the boiler-room force is intelligent and conscientious.

The results obtained in a steam plant depend considerably upon this condition, and are likely to be materially poorer than our figures indicate; while the defective conditions may not become apparent until heavy losses have been incurred, and even then the fault will be difficult to locate because there are such various types of appartus and so many to be considered. The efficiency of a Diesel engine plant is much less affected by the character of the personnel, and negligence is immediately and readily detectable.

Figure 3. General Description of Busch-Sulzer Type B. Four Cycle Engine

The Busch-Sulzer Type B Diesel is of the vertical four cylinder single acting, four cycle enclosed crankcase design. The standard speeds have been selected with reference to the speeds of alternating current generators and the engine is built for heavy duty service with all parts accessible for inspection and adjustment. The bed place is made in once piece with saddles or bridges, between each pair of cylinders which are bored to receive the main bearing shells.

HEAT UNIT IN FUEL, CONSUMED PER BRAKE HORSEPOWER PER HOUR.

Load Per Cent. of Rated B.H.P.	Simple Non-condensing Corlis Engines		Compound Condensing Corliss Engines		Triple Expansion Steam Engines		Steam Turbines		Diesel Engines

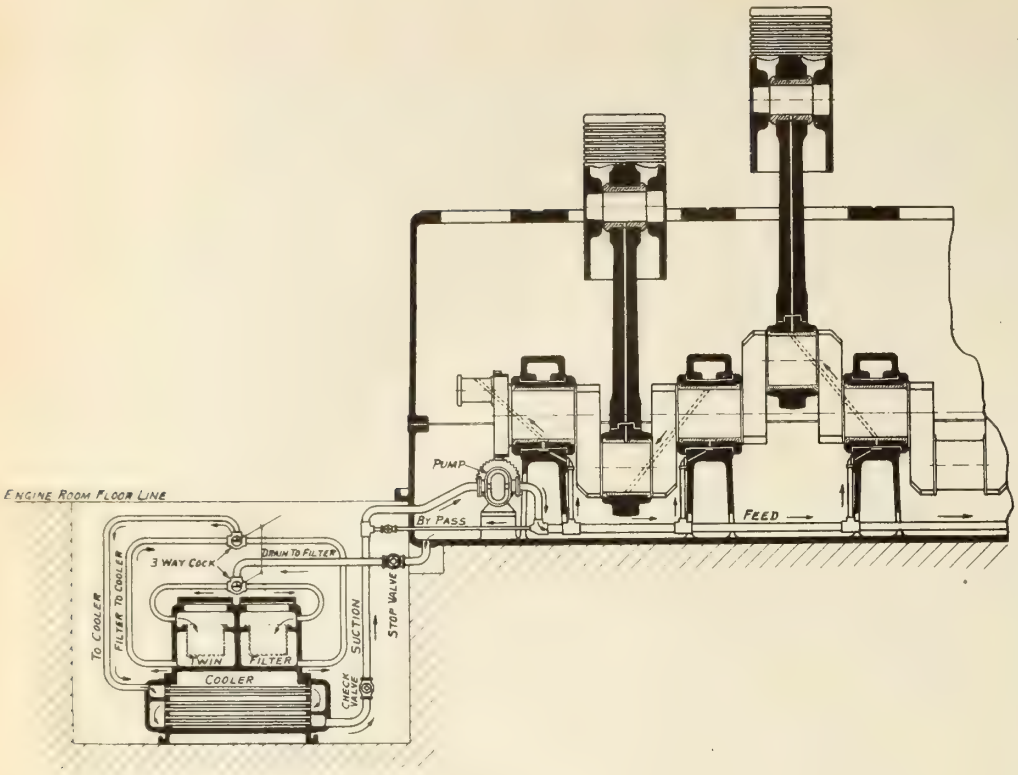
For steam plants add allowance for stand-by, according to character of load.



FORCED LUBRICATION SYSTEM.

The enclosed crank case is supplied with hinged doors for making inspection of the crank pins and moving parts and for making adjustments. The working cylinder is provided with a removable lier, the outer jacket carrying all axial stresses. The upper end of the cylinder liner makes a water tight shoulder joint with the jacket, the liner being free to expand downward, as it is supported in a fixed manner at one end only.

The cylinder heads are of symmetrical design and contain the pockets for the inlet valve, exhaust valve, fuel valve and air-starting valve, all of which work in a vertical position.

The inlet and exhaust valves are of the Poppet type, held on their seats by springs. The exhaust valve is provided with means for relieving the compression in the cylinder. When starting the exhaust valve levers are split to provide for the removal of the valve and cage with the least possible dismantling.

A shaft, carrying all the cams for operating the valves, extends along the top of the cylinders, in an entirely closed case, and is driven directly from the crankshaft, at half its speed, by a vertical shaft located at the fly-wheel end of the engine.

The spring-loaded, centrifugal type, enclosed and self lubricating governor, controls the amount of oil delivered to each cylinder by varying the time of closing of the suction valves of the fuel oil pump.

The pistons are of the long trunk type, and are water cooled by a system of telescopic tubes on engines of 500 horsepower and over. The crankshaft carries the four cranks for the working cylinder and the small crank for the compressor.

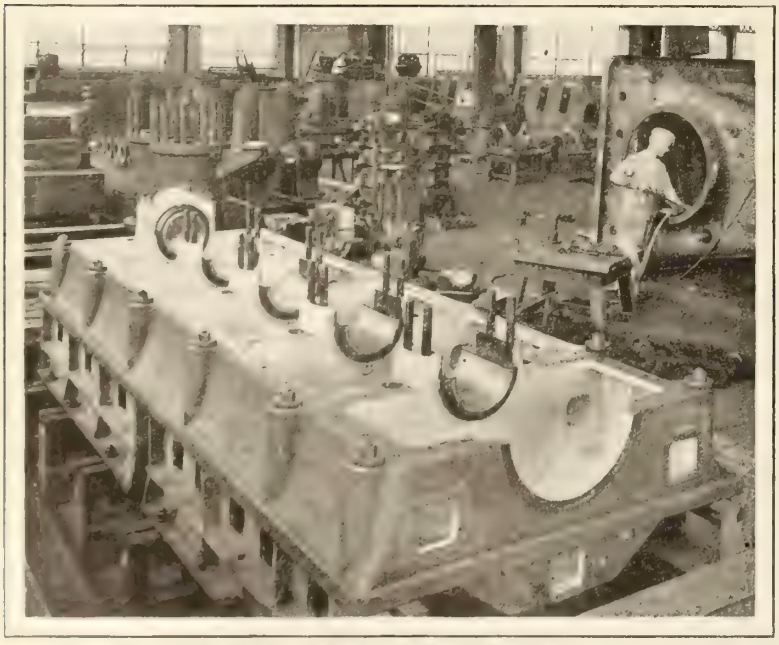
The main bearings are of cast iron shells, babbitt lined, and made in halves. The extension shaft is arranged to receive the flywheel and either generator or driving wheel between the engine and an out-board bearing.

The air compressor, for providing compressed air for fuel injection, is driven from the main crank shaft. It is a three-stage compressor and provided with adequate intercoolers and after-coolers to keep the air at a low temperature.

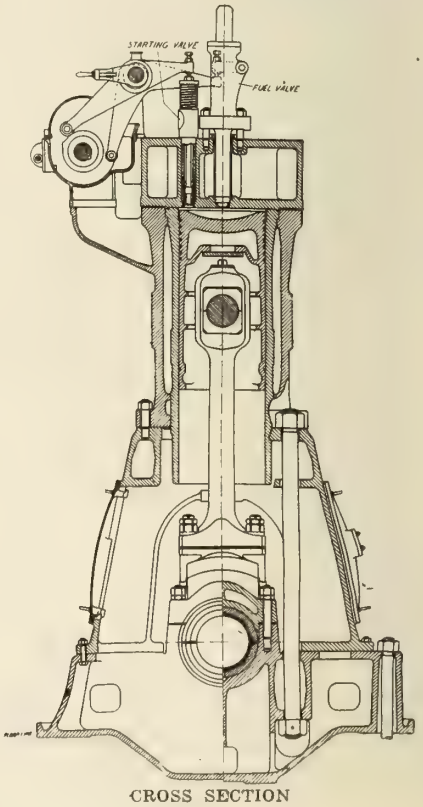
The engine is started with compressed air, furnished by the injection air compressor, stored in tanks so connected up with the compressor that they can be charged without in any way interfering with the operation of the engine.

All cooling water discharges into open funnels and individual pipes are provided from each cylinder.

The general lubricating system is a pressure system serving all main bearings, crank pin and piston pin boxes, vertical shaft thrust bearing, and all lower helical gears with a continual supply of oil under pressure. The oil, after passing through the bearings, is collected in



BEDPLATE FOR FOUR-CYLINDER ENGINE.



CROSS SECTION

the bed plate, returned to a twin filter and tubular cooler, from which it is taken by a gear driven positive displacement pump and again forced thru the bearings at a pressure of from 10 to 20 pounds.

A force feed oil pump is provided for lubricating cylinders. The engine presents a very finished appearance.

The Busch-Sulzer Bros. Diesel Engine Co. is the pioneer American Diesel engine builder, having completed, in September 1898, the first Diesel engine in the world to be placed in commercial service. During the past twenty-two years this firm has had experience in building over 500 Diesel engines, including both two and four cycle stationary and marine Diesels.

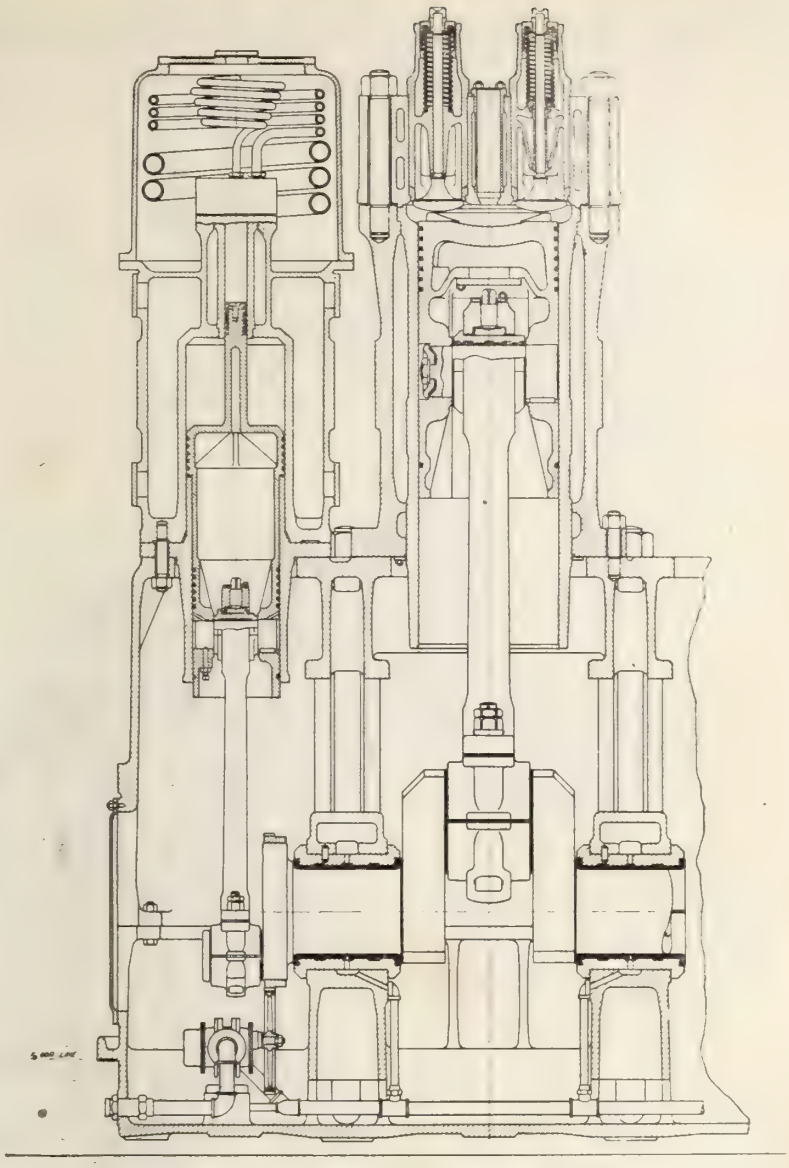
BOOK REVIEWS

We have received a copy of of the "Practical Electricians Pocket Book and Diary," price 2/6, published by S. Rentill & Co., Ltd., 36 Maiden Lane, Strand, London, W. C. The book covers a wide field, embracing every application of electricity to modern industry. All kinds of instruments are described, methods of testing, insulation, etc. Various features of the wireman's art are clearly described, including the various ways of making splices on cables. Fittings for indoor and outdoor work, both low and high tension, are dealt with. The various motive powers, steam engines, steam turbines, gas producers and gas engines, oil and petrol engines, and water turbines, each receive attention. The book is a very useful one to have for immediate reference and is interesting as comparing British practice with that on this continent.

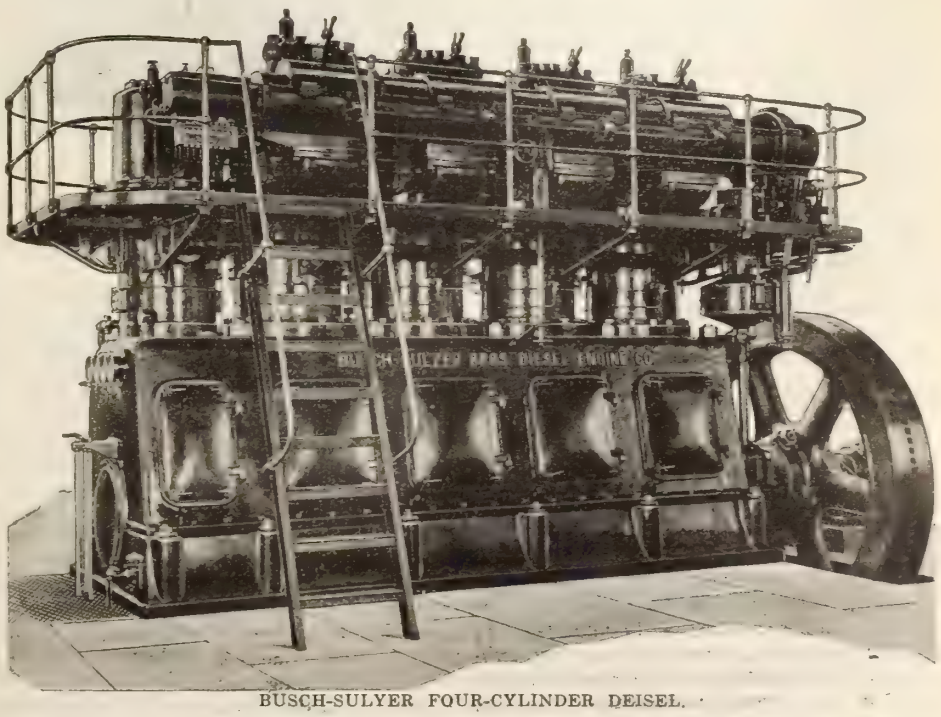
The Northern Electric Co. have issued a booklet dealing with electric power and lighting on the farm. The book gives a table of the various purposes to which electricity can be applied, and a description of the various sources from which electricity can be generated. Various installations are illustrated, as well as different types of engines and generators.

The Page Hersey Iron Tube and Lead Co., Ltd., have issued a hand book on the manufacture of wrought iron and steel pipe, giving a general description of the processes employed in each. A short history of the firm is included, tracing its development since its inception in 1902. Illustrations of the Company's mill at Welland are included showing various stages of the manufacture of both kinds of pipe.

According to a telegram received in the Department of Overseas Trade from His Majesty's Commercial Secretary to the British Legation at Warsaw, the opening of the exhibition of agricultural machinery, advertised to take place in Lemberg in June, has been postponed until the end of September.



SECTION SHOWING AIR COMPRESSOR.



BUSCH-SULYER FOUR-CYLINDER DEISEL.

The Radojet Air Pump and Its Operation

A Description of This Type of High Vacuum Apparatus is Given, as Well as a Problem Arising During its Operation, by Henry Wright

Chief Engineer Hochelaga Power House.

AT the present day when so many mechanical labor and steam saving devices are being placed on the market that the chief engineer who is trying to keep his plant up to date and save his employer money gets his brain in a swirl trying to solve the eternal problems, will its cost be too high? will its maintenance be out of reason and what place will it take in the operating field. Now, we all know that the prime cost of any article has always to be weighed in the balance of efficiency and maintenance. Some devices raise the efficiency but their maintenance is prohibitive and from an operating point of view are impracticable.

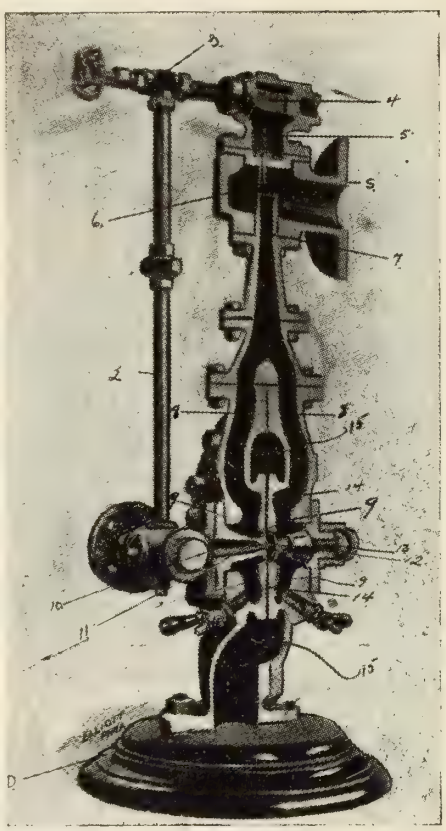
The principle of the jet is merely that of two ejecters in series, and like the ejecter may be looked upon from a Thermodynamical view as a perfect heat unit (less slight radiation losses.)

It is extremely simple in construction. There are no moving parts to be oiled, it takes little space, requires no foundation and is almost noiseless. It is quickly superseding the reciprocating unit or the old style of air pump and also the intrainment pump. I don't propose to enter into the great objection against the last mentioned pump because they are well known to all engineers. Removing air by steam was known and practised as early as 1868 but was never developed to produce the high vacuum commercially and has only become useful since turbines became the standard primo mover. The patent belongs to C. H. Wheeler of Philadelphia, who has, by numerous experiments brought it to the present state of perfection.

As the cut shows it consists of two steam ejecters in series. The upper is called the first stage by the makers but it is the second to come in operation and the lower is called the second stage and is the first to come into operation. The steam enters through the opening L through a strainer, this is seen more clearly by looking at the jet complete in Fig. 1, it then passes up pipe 2 to angle valve 3 through strainer 4, expansion 5, across suction chamber 6 of the first stage ejecter which is in communication with the condenser through the suction opening S.

The steam expands in the nozzles leaving with a very high velocity and when passing across suction chamber 6 entrains the air and vapors to be compressed. The mixture passes into the diffuser 7, from where it is discharged at higher absolute pressure than that of the air entering at S into a double passage 8 communicating with suction chambers 9 of the second stage. These two suction chambers 9 are annular and give the commingled fluid a large entrainment surface.

Steam is simultaneously delivered through the strainer 1 into passage 10 which communicates with the annular expansion nozzle formed between two circular dises, 11 and 12, Disc 12 may be adjusted towards or away from disc 11 by the adjusting screw 13 to vary the cross section of the nozzle passage this will change the expansion ratio of the steam. The steam delivered radially by the annular nozzle 11 and 12 expands. leaving it as a jet of very high velocity in the form of a sheet and in passing across suction chamber 9 entrains the air and steam coming from the first stage and carries them into the annular diffuser 14 thereby compressing the mixture to atmospheric pressure and discharging it into casing 15 which has the discharge opening D.



SECTIONAL VIEW

On looking at the Photos 1, 2, and 3, a clearer understanding may be got. First in the double passage 8 this is belonging to the casting but outside the casing and enters the casing behind the nozzle 1 and 1 in looking over Figure 1 and Print 2 and 3, it will be observed that these nozzles consist of two discs one with a passage through, the other with a slight cone projection, this is where the steam from the second stage begins it operation. The first stage steam is discharged from behind these discs. I may say that these discs are of very highly tempered steel with no mark of wear after two years service. No. 2 and 2a in the Prints are the annular diffuser and are part of the casing and simply machined at the back to a depth of 2 inches. At the bottom of Print 2 is the discharge D and a baffle plate is seen here. The reason is obvious, if one will think of the characteristics of the steam. Print 3 is a photo of the back plate and is bolted on to the section shown in print 2. Print 1 is the whole section with the back plate taken away.

The sections when bolted together leave a space between the annular diffusers of .30 of an inch. The lower nozzles 11 and 12 are regulated according to pressures and superheat.

With 150 lbs. pressure and 190 deg. Fahr. superheat, they are about 3-16 of an inch apart. Now from the operators' point of view they are exceedingly good and once set require no attention. We have them about 10 ft. from the main floor with 3 gauges attached; the Boiler pressure, the Reduced pressure, and the vacuum guage. They work most economically and steady at about 150 lbs. This allows for a variation of 20 per cent. fluctuation of Boiler Pressure, should priming take place in steam line they recover themselves readily. I should have mentioned that a reducing valve is placed in the steam line, attached to the jets.

Before entering into the steam consumption and efficiency of these jets, I would like to give a little experience that befell me about 6 weeks since.

This jet belongs to a pair connected together and attached to our No. 1—12,500 K.W. Curtiss Turbine during a heavy load the vacuum was observed to suddenly fall from 29.4 to 24 inches, in a large unit of this class, one can readily see how the steam flow meter would climb up, and the operating engineer get very busy with a torch looking for trouble. After an hours careful survey everything seemed O.K. so back to the jets. Here every valve strainer etc., was tested to see if it was an obstruction, again the O.K. so we reduced to ¾ load and shut one jet down when up went the vacuum gage to 28.5. (At the end of my article I will give a few words on correction of absolute back pressure and mercury columns of vacuum guage corrected to temperature of atmosphere). The other jet was put in service and the second one shut down. Down went the mercury to 24 inches again. with a relieved "Oh!" the chief operator (engineer) smiled and said "found," and the offending unit was placed in the repair shop and opened up. The closest scrutiny was given to every movable part, and we discovered a slight crack on the inside of casing which is shown on Print 3 but after test this only proved to be a surface rupture and under 30 lbs. steam test proved tight. The nozzles were readjusted but all to no purpose after a lot of head scratching we decided to ask the outside advice, a man came down and after advising, testing, etc., walked away disgusted. My chief operator and myself looked at one another, each trying to read the others mind, and we both hit the mark with the same idea. Were the diffusers correct?

We set to work with surface guage on the test plate and found the back annular dif-

user was sunk down 1-32 of an inch as shown in Print 3—3 and 4 to prove our theory was correct we took the back plate of one of our other jets, bolted it up in place of the suspected one, and tested. Good vacuum to standard, and the other back plate condemned. Now here is a nice problem touching on Dynamics and Physics for some one to try and work out, however space won't allow here, but try and find the cause why one should do the work and yet when the other one was put in they both failed. One jet is really sufficient for a .80 load factor, why should this not have kept the other to the same vacuum when both are connected to same steam pipe and same exhaust. I have my theory which will be given with a later article on Thermodynamics.

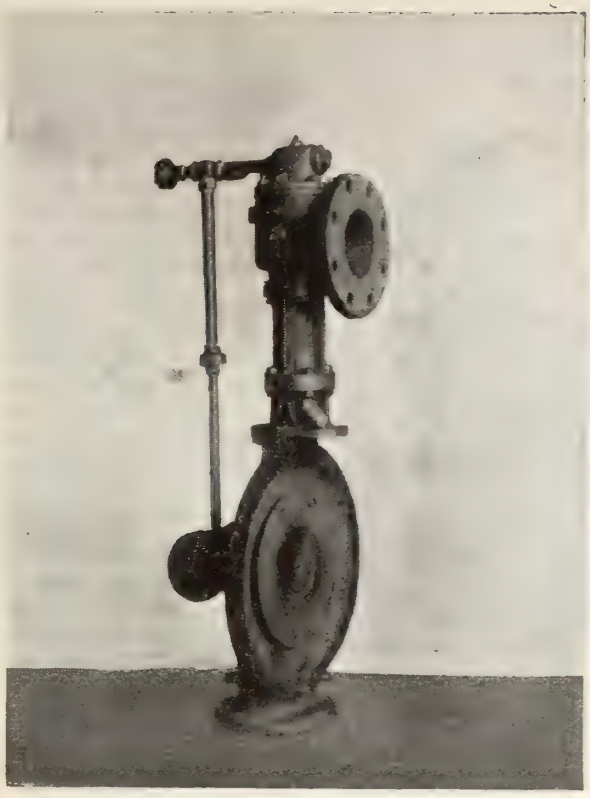
Now we will compare this unit with the ordinary reciprocating fly wheel air pump of air pump of the Blake class.

The ejecters together will use 3,000 lbs. of Boiler Steam per hour, at 150 to 190 lbs. pressure per sq. inch, at 190 deg. Fahr, superheat and the back pressure about ½ lb., at 1 inch total pressure. These pumps together will remove 13 cubic feet of free air per minute (or 13 ÷ .225=58 lbs.) orifice test room conditions 70 deg. Fahr. This works out (allowing for 25 per cent. over load) at 1 1-3 per cent. of total steam consumption. Now the usual practice of reciprocating air pumps is to allow .00024 h.p. per lb. of exhaust steam, this with a 60 per cent. efficiency works out at 1 per cent. of total steam, but weigh in the balance the maintenance cost, space and attendance and the jet has the balance in its favor. Before concluding this article I would like to place a few formulae that are not as seriously studied as they should be considering the price of coal, at present time.

Condensers

The primary object of a condenser is to reduce the back pressure on the piston although the recovery of the condensate is of great importance. A great many engineers are led to think that the air pump creates the vacuum, this is an error. The air pump merely removes the air which leaks in or carried in with the condensed steam and so preserves the vacuum already formed from being impaired gradually. If a dry air pump, handling air and vapour alone is shut down, a tight condenser will operate for a considerable length of time with no change except a slight drop in vacuum. We all know that air in a condenser is bad, it not only causes work for its removal but cuts down the efficiency owing to the low thermal conductivity of the air. But on the other hand when the pump is removing the air it necessarily removes the water vapour with the air. We don't benefit the vacuum by pumping out the vapour as the pressure of the vapour in the condenser is determined by the temperature and any vapour removed is instantly replaced. But we can't remove the air without handling the vapour. In studying the design of condensers always keep in view that the air and vapour are taken from the coldest part of the condenser, this lessens the work of the air pump by reducing the tension of the vapour and removes the air in a less rarefied state.

A great many engineers are not thorough enough in studying their mercury column attached to the condenser. Some time ago I was in a plant when the engineer pointing out his mercury column remarked good vacuum. I asked him, "What is the correct reading?" He looked at me then at the column and then said, "That is," pointing to the column. I asked for the barometer. I looked at it and at the Thermometer and remarked, "I am afraid not." "Well! show me how it is not," he answered.



RADOJET WITH BACK PLATE REMOVED.

Now with water as cooling medium the minimum temperature to which vapour can be reduced is 32 deg. Fahr. This corresponds to a pressure of .0886 lbs. per. sq. in. or 0.1804 inch of mercury. This represents the lowest possible pressure in practice in a condenser.

We all know that vapour condensed in an air tight vessel results in reduction of pressure but if open to atmosphere condensation will continue, but the pressure will remain at atmospheric level. The standard atmospheric pressure at sea level and at 45 deg. latitude is 14.6963 lbs per sq. in. corresponding to a mercury column of 29.921 inches in height the temperature of the mercury 32° Fahr. all steam tables are based on this but read of tests and statistics with the words refer to a 30 in. Barometer. I am giving two examples to show how the engineer can correct his mercury column and obtain the true reading. The formula or equation for correction to any temperature is:

H. Freight of mercury column corrected to temperature t.

h = observed height of mercury.

t_1 = observed temperature of mercury column.

t = temperature to which column is to be referred.

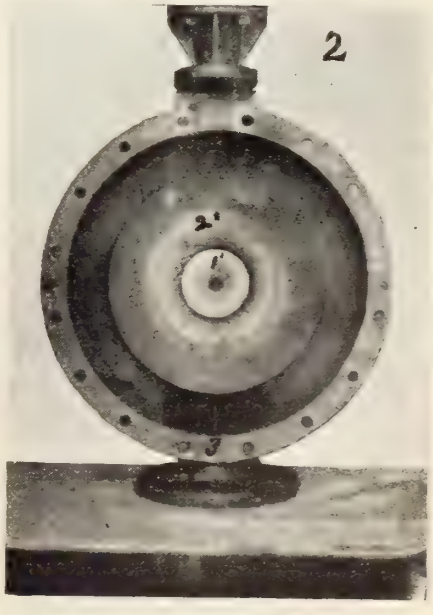
Now we will see more clearly if we take an example. Suppose our vacuum gauge reads 28.52 inches and the temperature is 80° F., then we look at the barometer and read 29.85 inches, the temperature there is 62° F. we will now transfer the readings to a 32° F. standard:

$H = 28.52\ [1 - 0.000101\ (80 - 32)]$
$28.52\ [1 - 0.000101 \times 48]$
28.52×0.995152
$H = 28.38$ for the vacuum gauge.
$H = 29.85\ [1 - 0.000101\ (62 - 32)]$
$H = 29.77$

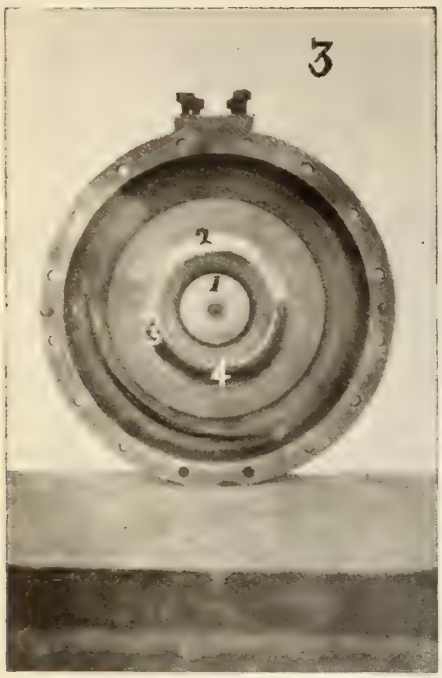
The absolute back pressure = 29.77 — 28.37 = 1.40.

1.40 absolute back pressure

Vacuum referred to a 32° standard =



SHOWING DIFFUSER DISC.



29.92 — 1.40 = 28.52

We will now transfer it to a 30 inch barometer. To do this, we must increase the temperature of the mercury, the height of the mercury must be increased from 29.921 to 30 inches by increasing the temperature of the mercury from 32° to 58.15° F. Then if the barometer and vacuum gauge readings are corrected to this temperature, the difference between the figures will give the absolute pressure in inches of mercury. According to the A. S. M. E. Power Code, a 30 inch barometer refers in round numbers to standard atmosphere with mercury at a temperature of 78°. We will use the same readings as before except we use 42° F.

H = 28.52 [1 — 0.000101 (80 — 58.15)]

H = 28.46. Readings for vacuum gauge.

H = 29.85 [1 — 0.000101 (42 — 58.15)]

H = 29.9. Reading for barometer.

29.9 — 28.46 = 1.44. Absolute back pressure.

30 — 1.44 = 28.56. Vacuum referred to a 30 inch barometer.

Editor's Note

This is an interesting case of trouble, and we invite our readers to forward their opinion of the cause. Those who have had no experience with the actual operating should be able to form an idea from the description. Let us hear from you on the matter.

A BOILER TUBE FAILURE

In a recent issue of the Journal of the South African Institution of Engineers, Mr. T. G. Otley described a case of boiler tube failure. The tube in question was in a bottom row of a water-tube boiler and was 3¼in. outside diameter and No. 7 gauge. The tube opened out for a length of about 10in., and as a result of the burst a large proportion of the fire was blown out of the furnace and the boiler house was filled with smoke and steam.

The failure, said Mr. Otley, is of more than usual interest, insofar as it very clearly illustrates a theory which he has held for some considerable time. When the burst occurred the furnace was fired and with a high quality Wetbank district pea coal with high furnace temperature —approximating, he judged, to about 1,350 deg. Cent., and no doubt the boiler was doing something more than its full load output. The calculated output was about 46,000 lb. per hour. It is, of course, well-known that in boilers heating surface nearest to the furnace does a disproportionately large fraction of the work. The botton row tubes in water tube boilers are worked very hard, but under normal working conditions they come to no harm, because the water is in contact with the inside surface of the tube and the metal cannot be overheated. Assume that the furnace temperature is, say, 1,300 deg. Cent., the temperature gradient across to the wall of the tube is a very sharp one—i.e., down, to say, 200 deg. Cent. the temperature on the water side—but further assume, as is reasonable under certain conditions of working, the steam bubbles attach themselves to the wall of the tube, then the temperature gradient is altered, and while remaining the same on the furnace side, the temperature may easily rise to 700 deg. Cent. or 800 deg. Cent. on the steam side, under which condition dissociation of the steam will occur and the metal on the steam side will become oxidised, forming thin layers of oxide. With the bursting of the steam bubble, water at approximately 200 deg. cent. temperature comes in contact with the tube, which contracts and the oxide cracks away. One can imagine this process being repeated until the sound metal is reduced very much in thickness until finally it is unable to resist the pressure combined with the temperature, and it then opens ont and bursts. Careful measurements of the burst tube showed that it had stretched very little, but the thickness of the tube nearest the fire, where it burst, came down almost to a knife edge. On the other piece of tube adjoining the burst an incipient blister was forming, and iron oxide on the steam side was clearly in evidence. It was also clear that some of it must have been cracked off and swept away by the rush of steam and water. The trouble cannot be accounted for by the quality of the material, which was excellent in every respect. The moral to be drawn is that when boilers are to be worked very hard it is of the first importance that the feed water should be of excellent quality, and that the lower tubes should be cleaned at fairly frequent intervals to prevent anything except the slightest scale adhering to them. As a matter of general practice Mr. Otley said that he put the turbine cleaner through the three bottom rows of the tubes every 1000 to 1500 hours.

ANNOUNCEMENT

The Worthington Pump and Machinery Corporation announce that in addition to their general line of hydraulic machinery, which they have manufactured since 1840, they have now undertaken the manufacture of all kinds of water-power machinery. This will include apparatus for low, medium, and high head service, including oil pressure system, water wheel governors and other auxiliaries. They will also manufacture hydraulic turbines, from their own designs. The Worthington Co's office is at 115 Broadway, New York.

In a recently published report upon the possibility and desirability of installing an industrial electrical network in Spain a scheme is outlined in which the main source of supply would be the waterfalls of the country, especially those of high head. The country is especially favored in this direction, because high water prevails at different seasons in different parts of Spain—in the Pyrenees in spring and summer, and in other parts of the country in winter. A careful investigation of the water power resources available has shown that a total of 2,000,000 kilowatts could be generated—excluding from the calculation falls yielding less than 2000 kilowatts. The proposed network, would, as far as convenient, join up the main centres of production and consumption, with Madrid as the centre of consumption. The total length of lines to be constructed would be 4810 kiloms. The report recommends the preliminary construction of a network for 300,000 kilowatts, which is about the power already available from other sources. The old systems would be joined up to the new one, thus giving initially an amount of 600,000 kilowatts available for consumption.

BILL

An Act to Amend the Stationary and Hoisting Engineers Act

His Majesty, by and with the advice and consent of the Legislative Assembly of the Province of Ontario, enacts as follows:—

Short Title

1. This act may be cited as The Stationary and Hoisting Engineers Act, 1920.

9 Geo. V., C. 37, Repealed

2. Section 4 of The Stationary and Hoisting Engineers Act, 1919, is repealed and the following substituted therefor:

Board of Examiners

4.—(1) The Lieutenant-Governor in Council may appoint a board of examiners consisting of three or five competent and independent engineers practically conversant with the construction of boilers and the operation of steam plants, who shall hold office during pleasure, and, subject to the regulations mentioned in the following section, shall prescribe the subjects in which candidates for certificates of qualification as stationary or hoisting engineers shall be examined, and shall conduct or provide for and supervise the examination of candidates and report thereon to the Minister.

Staff of Board

(2) The Lieutenant-Governor in Council may appoint such examiners, officers, clerks and servants of the board as may be deemed necessary.

A Discussion of the Uniflow Steam Engine

A Paper Read Before the Manchester (England) Association of Engineers, by Mr. Henry Pilling, M. I. Mech. E., Goes Fully Into the Principles of This Engine.—Part I.

THE uniflow steam engine includes the characteristic feature of one double-acting cylinder, fitted only with one steam inlet valve at each end and no exhaust valves.

The exit of steam at the end of each working stroke is very simply brought about by the following ingenious device. The cylinder is made long enough to accommodate a piston, which has a total length of nearly equal to the stroke of the piston, usually about 10 per cent. less. The cylinder barrel is prepared with exhaust ports or slots round its circumference at about the centre of the length of the barrel. These slots have a length, in a longitudinal direction, equal to about 10 per cent. of the piston. The three factors, i.e., one cylinder with inlet valves only, a piston a little shorter than the stroke of the piston, use of exhaust slots in the centre of the barrel, form the distinctive constructional features of the uniflow engine.

The sectional drawing—Fig. 1—shows that while the inlet valves provide for the admission of steam in the usual way, the necessity for exhaust valves has entirely disappeared owing to the piston just before the end of its stroke in either direction, uncovering the barrel slots which lead to the condenser. Consequently, a free and ample opening is provided for the exit of steam and for the rapid reduction of pressure in the cylinder to the condenser pressure. On the return stroke, the piston promptly covers and closes the slots, compression begins, and because of this prolonged compression which lasts nine-tenths of the stroke, the characteristic indicator diagram of the uniflow engine is obtained.

The question will now be asked, But why is a single-cylinder uniflow condensing engine more economical than a compound two-cylinder condensing engine? The cause of the improvement is to be found in reduced loss of heat to the walls of the cylinder, and in reduced heat losses to the condenser. In other words, the uniflow engine condenses less steam inside the cylinder while working than does a compound engine. With an ordinary compound engine using superheated steam, the steam would enter the high-pressure cylinder at a pressure of, say, 175 lb. absolute, and at a temperature of about 520 deg. Fahr. It would leave the high-pressure cylinder at about 45 lb. absolute pressure, and temperature 275 deg. Fahr. During the exhaust stroke the pressure would average 35 lb. absolute, and temperature 260 deg. Fahr.

In the low-pressure cylinder the inlet pressure would average 30 lb. and temperature 250 Fahr., at exhaust opening 10½ lb. and temperature 196 deg. Fahr., and during exhaust stroke, say, 3 lb. absolute with a temperature about 142 deg. Fahr. Now note:—In a compound engine, fitted with inlet and exhaust valves at each cylinder end, the steam enters, pushes the piston down the cylinder, retreats when its work is done along the same path back to the inlet end, and finally is all swept out by the returning piston through the exhaust port, which is open the whole time of the return stroke. In such an engine steam enters both high-pressure and low-pressure cylinders, only to find cylinders cooled during the previous exhaust stroke by the presence of the comparatively low pressure, low temperature exhaust steam, and doubly cooled by the fierce rush of this cooling vapour against the walls and passages, which presently admit the next charge of hotter inlet steam. Obviously, then, condensation is bound to be great.

In a uniflow engine, on the other hand, how changed for the better are the termal conditions. The steam retraces its path. It keeps on in the same direction. The current is "one direction flow," i.e., "Uniflow." When the steam has done its work it is rapidly exhausted through the opened slots, which remain open to the condenser temperature on-

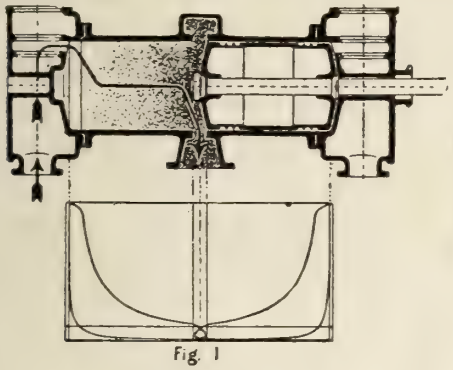


Fig. 1

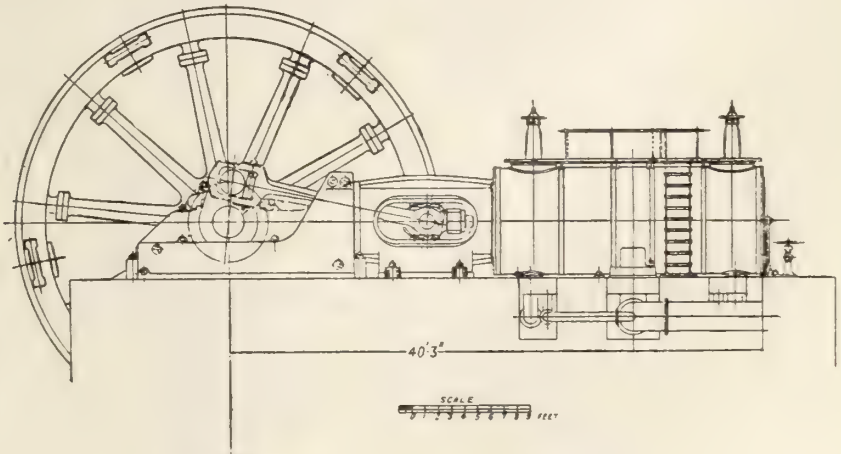

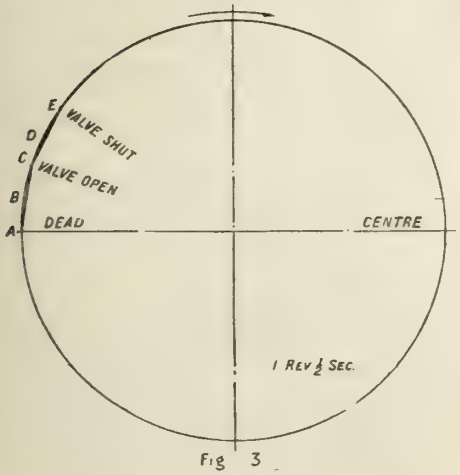

Fig 3

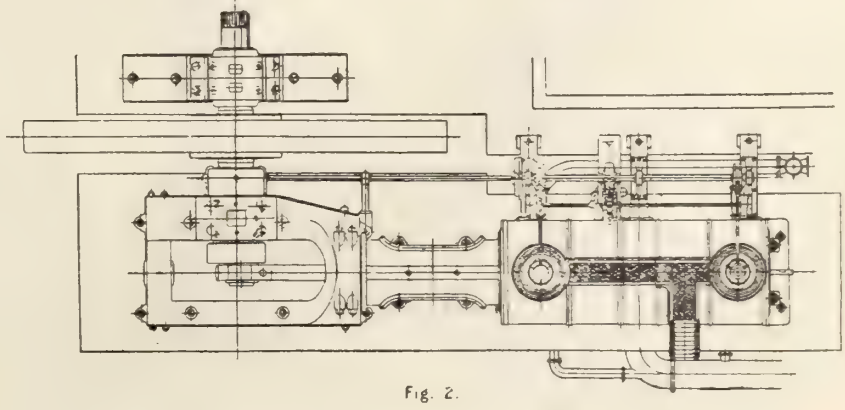

Fig. 2.

ly one-third of the time required in a compound engine. In no manner does it rush past, scour or sharply abstract heat from the hot surfaces at the inlet end of the cylinder. Such an abstraction of heat in the compound engine is loss, and the avoidance of such loss in the uniflow engine constitutes profit.

That these statements are well based may be proved by touching a uniflow cylinder when at work. The cylinder will be found hot at the two ends—i.e., full original steam temperature—and cool at the centre of the barrel—i.e., condenser temperature only. The cylinders of a compound engine, on the other hand, are uniformly hot all over, but at a temperature less than the inlet steam temperature, and therefore subject to the condensation evils. This gain is accentuated by the simplicity of the means by which it is achieved. The following is a comparison of the parts required in the types of engine referred to:

Uniflow Engine

One piston.
Two inlet valves and mechanism.
One piston-rod.
One piston-rod packing.

Compound Engine

Eight inlet and exhaust valves and mechanism.
Two piston-rods.
Four Piston-rod packings.
Two back slides.

It is important, however, that the exact sphere of usefulness of a uniflow engine should be rightly apprehended. It is the best type of engine, and is recommended for those conditions where condensing water is available and assured, and where the direction of rotation is continuous. For permanent non-condensing working, the choice will be according to circumstances. For reversing engines, winding engines and the like, other types of engines are usually to be preferred.

Thus, the "Uniflow" is especially suited for the driving of textile mills, paper mills, tin-plate mills, sheet mills, continuous-running non-reversing rolling mills of all kinds, timber mills, dynamo driving and all similar purposes, and the largest sizes required can be made. For example, I have on hand at the present time what I believe to be the largest uniflow engine in the world, i.e., with cylinder 60 in. diameter, 6 ft. stroke. A drawing of this engine is given in Fig. 2.

Valve Gears

One of the characteristic features of the uniflow engine is a normal working cut-off ranging from 5 to 10 per cent. of the stroke. This is in marked contrast to the cut-off in compound engines, which ranges normally from 25 to 50 per cent. of the stroke. In the uniflow engine the normal period available between the opening and closing of the steam inlet valve is thus from one-fifteenth to one-tenth of a revolution, and in the compound engine one-sixth to one-fourth of a revolution. In compound engines earlier cut-off than one-sixth give trouble with Corliss valve trip gears, and consequently the use of this class of gear and valve for very variable loads frequently requiring zero cut-off has been gradually abandoned.

With uniflow engines the mechanism adopted for opening and closing the valves in the exceedingly small time available is usually of the percussion or positive type; that is to say, the valve is pressed open by some form of cam gear and forcibly closed by means of a strong following-up spring. The word "percussion" is used advisedly in order to draw careful attention to the fact that with fast-running engines the operating valve forces are apt to be in the nature of a hammer blow. Consequently, if noisy working, severe wear and tear, and working troubles generally are to be avoided, the design must be theoretically sound, the proportions adopted must be ample, the workmanship and material of the very highest grade and the lubrication perfect.

As an example of the method of approximately calculating the inertia forces involved, both on piston and valve, we will take the case of an engine 3 ft. stroke running at 120 revolutions per minute, with a cut-off of 10 per cent. and a valve lift of 3/16 in. at this cut off. At 10 per cent. cut-off the movement of the crank pin from the dead centre is—very nearly—one-tenth of the crank-pin circle. The crank pin velocity is 18.85 ft. per second. The

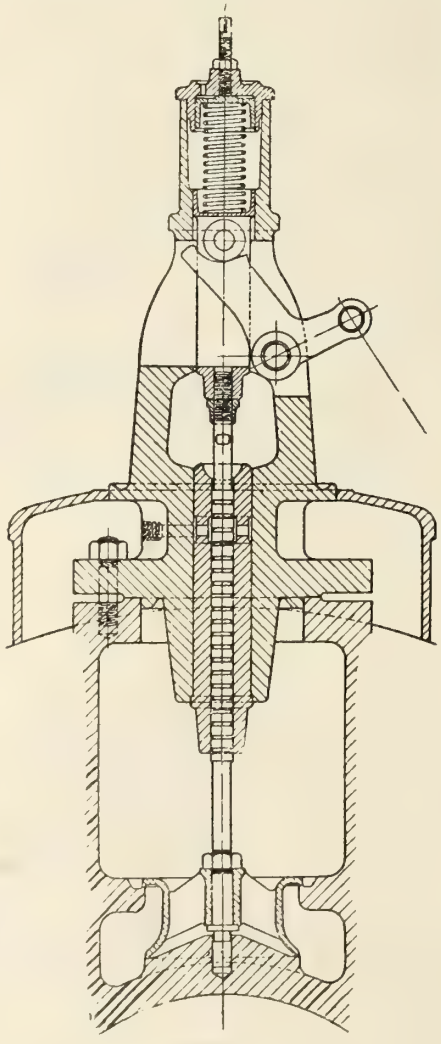

FIG. 6.

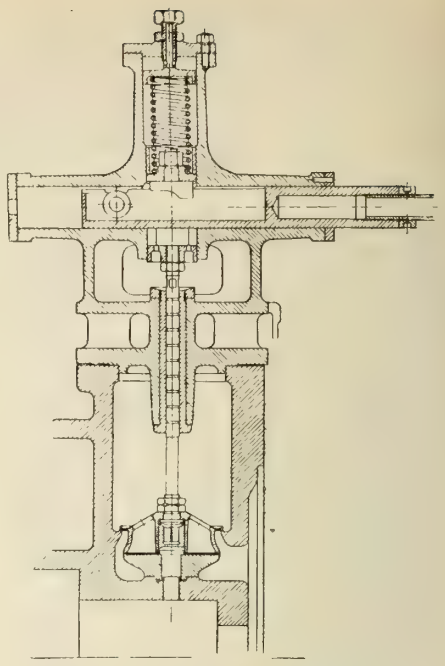

FIG. 7.

time for each revolution is half a second. The time available for opening and closing the steam valve is 1/20 sec.

To compute the forces necessary to start a piston and rod into motion from the end of the stroke at the velocity imparted by their connection to the crank pin, it is customary in drawing-offices to assume that the weights are tied to the crank pin and to calculate the centrifugal force they would there exert. This force is equal to the "dead-centre" inertia force we are seeking.

The usual formula is used as follows:

$$F = \frac{W v^2}{g r}$$

F = centrifugal force per pound of revolving weight.
W = unit weight, 1 lb.
v = crank pin velocity in feet per second.
g = 32.2.
r = crank pin radius in feet.

Then for the case cited:

$$F = \frac{1 \times 18.85^2}{32.2 \times 1.5} = 7.4 \text{ lb.}$$

This 7.4 lb. is the force required to overcome the inertia of each pound weight of reciprocating parts affected. It is a considerable amount, and a designer must not be ignorant of it or ignore it when fixing the strength of parts.

Now, let us assume the same formula is applied to calculating the inertia resistance of a valve. In our particular case the lift is 3/16 in., and the total time for opening and closing is 1/20 sec. The opening and closing movements are equivalent in character to the outward and inward strokes of a piston which jointly take one revolution. Next, we will imagine the valve is opened and closed by the action of a crank of 3/32 in. radius (1/128 ft.), i.e., 3/16 in. stroke, making its complete revolution in 1/20

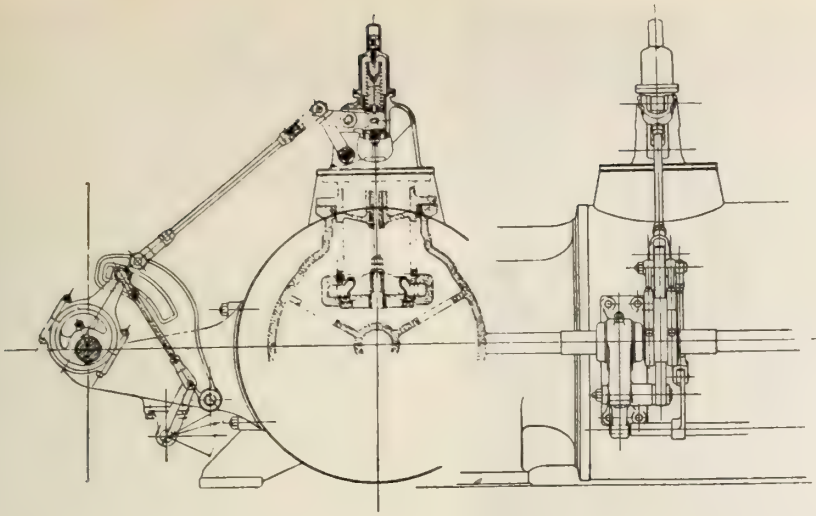

FIG. 4.

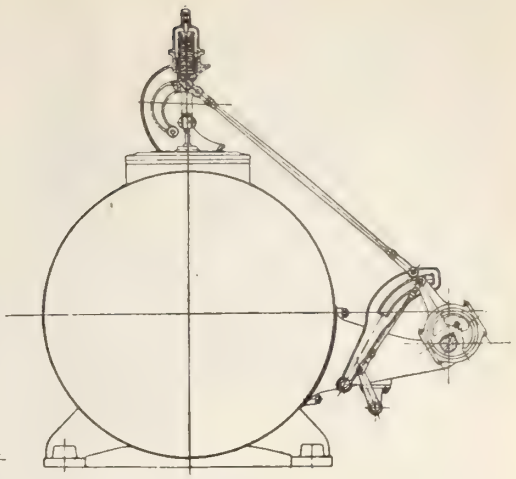

FIG. 5.

sec. The crank pin velocity is therefore:

$$\frac{3}{16} \times \frac{3.1416}{12} \times 20 = .98 \text{ ft. per second.}$$

The inertia resistance of the valve line for each pound weight moved is found exactly as in the case of the piston, thus:

$$F = \frac{W\ v^2}{g\ r} = \frac{.98^2}{32.2 \times 1/1=28} = 3.82 \text{ lb.}$$

This also is a considerable amount and must be taken careful note of by valve gear designers.

The preceding calculation for the valve assumes that the valve is moved at a variable rate of acceleration, as though worked by a crank. In actual practice the valve would not be so moved. The actual rate would depend on the type of valve gear, on the form of any cam or contact surfaces, and so on. It will, however, be useful to consider the case of a valve opening at a uniform rate of acceleration, as though moving freely under a steadily applied uniform force analagous to the action of gravity. Assume that the valve acceleration is uniform, while the velocity increases from zero at the beginning of the lift to a maximum velocity at half lift, and that half lift occurs midway in point of time between the beginning of lift and full lift, i.e., that the times for the first half of the lift and the second half are the same. Referring to Fig. 3:

A = valve begins to open, rest position.

C = valve full open, rest position.

E = valve shut, rest position.

B = assumed point of maximum velocity of valve when opening.

D = assumed point of maximum velocity of valve when closing.

A to E = one-tenth revolution = 1/20 sec.

A to B = one-fortieth revolution = 1/80 sec.

The time for half lift is then a quarter of the time from beginning of opening to closing of valcve:

$$= \tfrac{1}{4} \times 1/20 = 1/80 \text{ sec.}$$

Hence the valve, moving with uniform acceleration, travels:

3/32 in., or 1/128 ft. in t = 1/80 sec.

The acceleration is then given by the usual formula:

$$a = \frac{2\ s}{t^2} = \frac{2 \times 1/128}{1/80 \times 1/80} = \frac{6400}{64} = 100 \text{ ft.}$$

per sec. per sec. and the inertia force for each pound of the valve:

$$= \frac{100}{32.2} = 3.1 \text{ lb.}$$

This compares with the 3.82 obtained by the first calculation. The designer is now aware that if his valve and spindle, etc., weigh 30 lb., his applied forces during opening must be, under the assumptions chosen, of the order of 3.82 × 30 = 114 in the one case and 3.1 × 30 = 93 lb. in the other. But a similar force has to be impressed during closure, and if the valve is closed by spring action, the resistance of which opposes the ascent of the valve, there is a total resistance to opening of 114 + 114 = 228 lb. in the one case, or 93 + 93 = 186 lb. in the other. (The weight of the valve has been ignored in the above, as the spring may be correspondingly weaker and the total resistances are unaltered.)

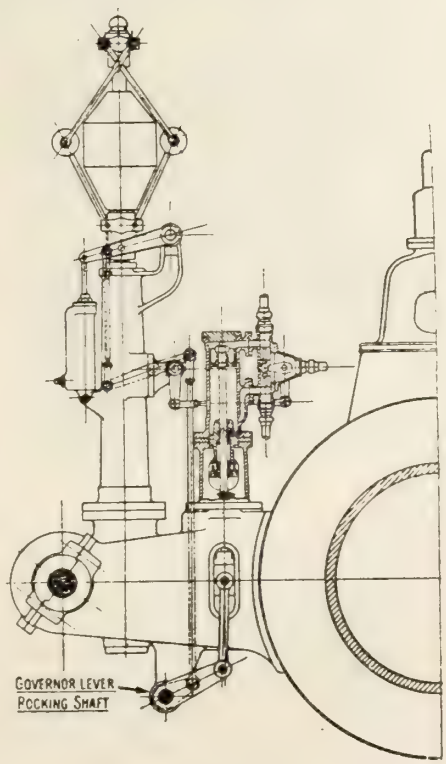

FIG. 8.

These figures, though based on assumptions which are modified in practice, nevertheless demonstrate in unmistakable manner the paramount necessity of keeping the valve lifts and weights moved as small as possible. Ignorance of the theoretical principles involved or failure to observe them in the design has caused many failures. In the actual design, in order to avoid initial hammer blow when, say, an operating cam or roller first comes into contact with the parts to be lifted, it is obvious that it will be best to bring the full force into action gradually rather than suddenly. This is usually done by suitably shaping the cam surfaces. The number of joints should be as few as possible, and the construction should be such that all slack is taken up before the real load comes on. It must not be the serious force required for lifting the valve which jams all the slack parts together.

The practical design has, of course, to be tempered to suit such factors as temperature effects and movements, elasticity and yielding of the mechanism under load, provision for rendering unavoidable wear and tear innocuous as far as possible, cost of manufacture and so on.

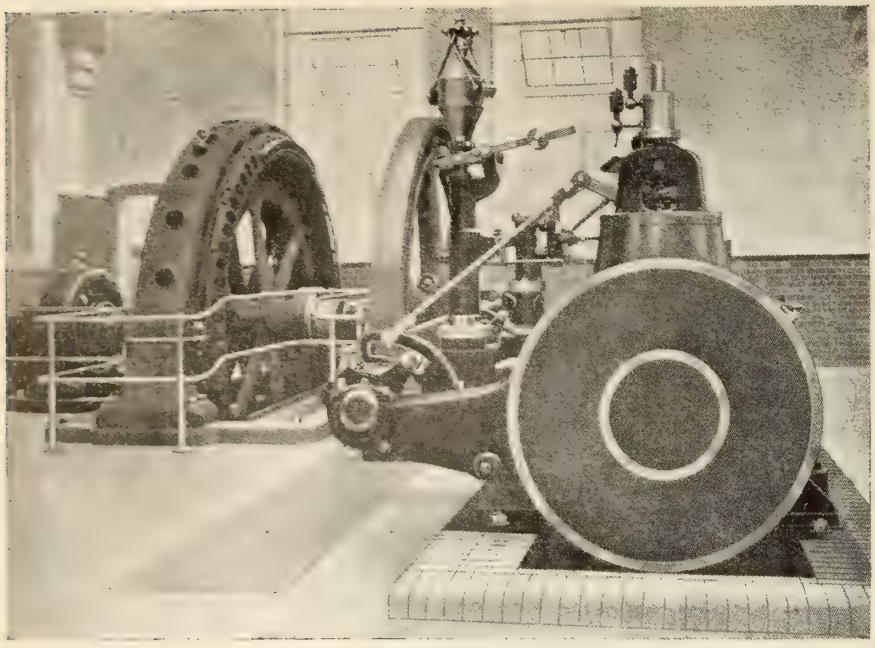
One gear is illustrated in Fig. 4, and in the half-tone engravings on page 454, which represent views of a 500 horsepower engine with cylinders 27 in. by 2 2 ft. 6 in.

This had the defect that wear caused slackness of a kind which absorbed part of the motion of the roller before lifting took place. Hence heavy knocking developed in due course due to the profile of the cam not being effectively used.

A solution to overcome this is given in Fig. 5. In this design the wear does not cause such disturbance. Other gears are shown in Figs. 6 and 7.

Governors

Hitherto the majority of uniflow engines have been made with layshaft



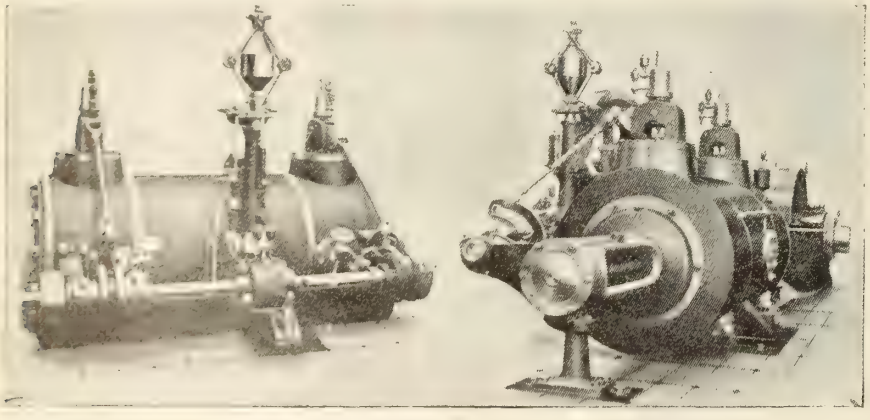
UNIFLOW ENGINE DIRECT CONNECTED TO ALTERNATOR.

governors. Governors of this class involve, as a rule, the use of two hinged weights, which, under the restraint of powerful springs occupy various positions according to the speed of the engine. Such governors are suitable for high speed, but are totally ineffective at slow speeds. Makers of uniflow engines have therefore found their principal market in engines with quick speed of rotation, such as, for example, 160 revolutions at 2 ft. 6 in. stroke.

There are many cases, however, for which uniflow engines are suitable, provided the speed of rotation can be made quite slow. For example, slow-speed pumping, slow-speed compressors or blowing engines, slow-speed direct-coupled rolling mill engines. In such cases it is not convenient to provide the necessary powerful governing force by means of a layshaft governor; some other type must be adopted.

My personal preference is for a frictionless governor of small power adapted to control the valve gear, not directly, but through a powerful servo-motor and oil relay. Such a device is shown in Fig. 8 and in the upper left-hand view on page 454.

By its use the powerful forces necessary for operating the valve gears of large engines are readily obtained. Such governors are also well adapted for use with speed variation devices to cover a wide range of speed.



SIDE AND REAR VIEW OF ENGINE.

WORKING TO MAKE USE OF LIGNITE

U. S. Department of Marines Has New Scheme Under Way to Use Large Deposits

Washington.—Efforts to make the lignite or brown coals of Texas, North Dakota, and other Western States so serviceable to that part of the country that will be unnecessary in the future to ship in other coals at great expense are to be inaugurated immediately by the Bureau of Mines, Department of the Interior, at New Salem, North Dakota, in co-operation with a company there.

Immense quantities of these lignites, constituting one-third of the fuel resources of the nation, are available in these states, but have been little used because of the great amount of moisture in them, their tendency to disintegrate when dry and their liability to spontaneous combustion. In fact, the difficulties have been so great in burning the lignite that the people have preferred to buy their coal in Illinois, Indiana, West Virginia, Kentucky, and Pennsylvania, bringing into their localities several million tons of coal that had been hauled an average of 1,000 miles and at a cost of nearly $5,000,000 in freights. The Bureau of Mines proposes to carbonize and briquet this raw lignite and develop a smokeless domestic fuel that will do away with the importation of domestic coal into this section of the country. By heating the lignite sufficiently to drive off the moisture and a part of the gases a char is obtained, which, in heating value closely approximates anthracite coal. The briquetting of this makes a very satisfactory household fuel.

An appropriation of $100,000 was made by Congress a year ago for this purpose and the Bureau of Mines has, after a careful survey of the entire field in which a number of the cities in these states have offered their facilities, selected New Salem as the place best fitted for the investigations, which will begin at once.

It is claimed in this process of carbonizing the lignite and making briquets out of it that not only is a superior domestic fuel created, but that valuable by-products are made, such as enormous quantities of gas to be used for fuel or power purposes, and a great amount of oils and tars.

Sliding Wage Scale.—Judge McLellan, chairman of the conciliation board sitting on the Ottawa Electric Railway dispute, suggested a novel way of coming to an agreement regarding wages, which may be recommended in the board's findings. His idea is that an agreement should be made covering a long term. The rates of wages should be increased in proportion to the increase in the cost of living. Every six months there should be a revision, and if living costs increase or decrease wages will increase or decrease in the same proportion. The figures taken as a basis would be those published in "The Labor Gazette."

Trouble at Peterboro.—The Canadian General Electric machinists' at Peterboro offer to the company to abide by the recommendations of the Board of Conciliation authorized by Senator Robertson, Minister of Labor, brought the following reply from Senator Nicholls to Mayor McIntyre: "The company declines to be represented on a Board of Conciliation in connection with the strike in Peterboro, and must also decline to accept any award of such board if appointed. We are still willing to grant the increases which were offered to the men before going on strike. We have advised the Minister of our decision." It was followed by another telegram, which simply reiterated Senator Nicholls' determination not to yield to the demands of the men.

A Course of Instruction for the Graded Certificate

We Will in This Course Go Through the Mathematical and Theoretical Work to Cover Every Grade of Certificate Issued by the Ontario Board

By T. H. FENNER

BEFORE proceeding with some examples of compound fractions, a short explanation of the use of the various signs employed and the proceedure to be followed in solving fractional statements will be useful. There is a definite rule to be followed in working out solutions, and if this rule is not observed, the results will be far from correct.

The Use of Signs

The commonest signs, of course, are the plus +, and minus —. Plus before a number means that that number is a positive quantity. A minus sign means that the number following is a negative quantity. Where several numbers are involved with these signs between them it means that the sum of all the negative quantities must be deducted from the sum of all the positive quantities. The result may be either positive or negative, and here is where the man with no knowledge of algebra may be puzzled. However, if he just casts his mind to a very familiar phenomenon of our winter climate he will understand it easily. If he looks at the thermometer on his way to work he may find it reads 15 below zero, or as it is usually printed, — 15. By eight o'clock it has gone up to — 10, and by 9 it has reached zero. At 10 it reads 5 above, or + 5, and stays there till 1 o'clock p.m. Then it comes down 5 degrees every hour, till at 5 o'clock p.m. it reads 20 below, or — 20. Now, the average temperature for the 11 hours would be found by adding the reading at every hour and dividing by 11.

Now the sum will be $-15 + (-10) + 0 + 5 + 5 + 5 + 5 + 0 + (-5) + (-10) + (-15)$.

This will give $-55 + 20 = -35$

$\frac{-35}{11} = -3.18$, or an average temperature of slightly over 3 degrees below zero.

Now, if we imagine any other body or figure or scale beside the thermometer as having a positive value, a zero point, and a negative value, there will be no difficulty with the plus or minus.

The multiplication sign is occasionally a stumbling block to the novice, as, instead of using invariably the ×, the sign is omitted altogether, or a small dot, something like a decimal point, is used. Where the signs are omitted altogether is when a literary formula is used, but the dots are used between numbers. A figure before a bracket as 3(6x9), means that the product of 6x9 must be taken 3 times. Letters denoting values when placed together, as PLAN in the well-known formula for horse power, are read as P × L × A × N, and an expression like 323.4.64 would read 323 × 4 × 64. However, this latter method is not used very generally, either the × sign being used, or the sign omitted altogether.

The division sign is written in a variety of ways. The best known, of course, is the ÷ sign, which is the one we first become acquainted with. Then there is the line used as in fractional quantities, as $\frac{2}{4}$ which means that two is to be divided by four, or $\frac{8 \times 11}{6}$ which means that the product of 11 × 8 is to be divided by six. Again a line is sometimes used as 12/2, which means 12 is to be divided by 2.

These four are what might be called the cardinal signs. There are several others which must be made familiar to the eye, and their meaning to the memory, so that when they are encountered in formulae, there will be no difficulty in arriving at the correct solution.

Of these, the various forms of brackets are among the most important, and are often stumbling blocks to the tyro. Their meaning and the way in which they are used must be thoroughly understood, or correct solutions will be a matter of chance instead of certainty. Bracket signs are classified as follows: The parenthesis (), the bracket [], the brace $\left\{ \right\}$, and the vinculum ——. The generic term covering them all is "signs of aggregation", and the meaning conveyed by any of them is that the numbers enclosed between them are to be simplified before any other operation is performed.

Take an expression such as $A = \frac{1}{2}(h + b)$, substitute figures for the letters, say, $A = \frac{1}{2}(3 + 5)$. This means that the sum of 3 and 5 multiplied by ½ will give the value symbolized by A. Take another: $4 + 6(8 \times 4 + 5) - 2 = A$. Now, here is where a very important rule is illustrated, in connection with the multiplication sign. Two numbers connected together by a multiplication sign must be simplified before those connected by any other signs. In this case the solution step by step is, taking inside the brackets first, the product of 8 and 4, added to five, multiplied by 6, plus 4, — 2.

The work is

$4 + 6(8 \times 4 + 5) - 2 =$
$4 + 6(32 + 5 - 2 =$
$4 + 6 \times 37 - 2 =$
$4 + 222 - 2 =$
$226 - 2 = 224.$

Now if the rule as to multiplying is not observed, the result will be entirely different. Suppose we were in simplifying the term in the brackets to add 4 and 5 before multiplying by 8, see what we should get.

The work would then be:
$4 + 6(8 \times 4 + 5) - 2 =$
$4 + 6(8 \times 9) - 2$
$4 + 6 \times 72 - 2$
$4 + 432 - 2$
$436 - 2 = 434.$

Now, when simplifying a formula in which several terms are bracketed, always simplify the terms in the inner brackets first.

Take the formula for finding the area of a segment of a circle, or rather one of the formulae, of which there are several.

$A = \frac{1}{2}[lr - c(r - h)]$

Substituting figures $A = \frac{1}{2}[8 \times 4 - 3(4 - 2)]$.

Simplifying $A = \frac{1}{2}[8 + 4 - 3 \times 2]$
$= \frac{1}{2}[32 - 6]$
$= \frac{26}{2} = 13$

Take another a little more complicated, as follows:

$$x = 4\{3 + [6 \times 9 - (2 + 4 + 3 \div 3)]\}$$
$$x = 4\{ + [6 \times 9 - 3]\}$$
$$= 4\{3 + [54 - 3]\}$$
$$= 4\{3 + 51\}$$
$$= 4 \times 54$$
$$= 216.$$

The rule to observe always is to simplify the expression in the innermost bracket first of all and when simplifying any expression to perform the indicated multiplication first, and the addition and subtraction afterwards. We have not dealt with the last sign of aggregation, the vinculum, because it is not used as a rule except in connection with the root or radical signs.

Having made clear the method of using the various signs, a few examples of complex fractions will be given, after which it will be possible to give the decimal system a little study.

Some Examples of Fractions

In example, the first step is to add the first terms of the numerator, 7-16 and 3-8 together, invert the fraction 9-27 and prefix the multiplication sign. Then proceed to simplify the denomina-

$$\frac{\frac{7}{16}+\frac{3}{8}\div\frac{9}{27}\div\frac{3}{4}}{\frac{5}{32}\times\frac{7}{8}+\frac{1}{2}}=$$

tor. It will be seen that there is a multiplication sign between the first two terms, followed by a plus sign. Following the rule, the multiplication is performed first, and then the addition. This brings the whole compound fraction to its simplest form, which shows that 39-16 is to be divided by 163-256, and the quotient divided by 3-4, or multiplied by 4-3. The various steps necessary are shown in the accompanying cut.

$$\frac{\frac{7+6}{16}\times\frac{27}{9}}{\frac{35}{256}+\frac{1}{2}}\div\frac{3}{4}=$$

$$\frac{\frac{13}{16}\times\frac{3}{1}}{\frac{35+128}{256}}\div\frac{3}{4}=$$

$$\frac{\frac{39}{16}}{\frac{163}{256}}\div\frac{3}{4}=$$

$$\frac{39}{16}\times\frac{256}{163}\times\frac{4}{3}=$$

$$\frac{13\times64}{163}=\frac{832}{163}=5\frac{17}{63}$$

Let us now take another example:

$$\frac{\frac{4}{3}\left\{\frac{5}{8}+\left[\frac{5}{16}-\frac{2}{3}\times\frac{1}{4}\left(\frac{3}{8}+\frac{7}{16}+\frac{3}{4}\right)\right]\frac{1}{2}\right\}}{\frac{4}{5}+\frac{3}{8}+\frac{1}{2}+\frac{3}{4}}$$

$$\frac{16}{24}+\frac{7}{32}$$

The first thing to do here is to simplify the expression in the inside brackets. The expression will then be:

$$\frac{4}{3}\left\{\frac{5}{8}+\left[\frac{5}{16}-\frac{2}{3}\times\frac{1}{4}\left(\frac{25}{16}\right)\right]\frac{1}{2}\right\}$$

Next, take the figures included in the second bracket which become 5-16 — 2-12, which gives 7-48. Taking off the inside brackets the expression now is:

$$\frac{4}{3}\left\{\frac{5}{8}+\left[\frac{7}{48}\times\frac{25}{16}\right]\frac{1}{2}\right\}$$

The next step will be to eliminate the remaining inside brackets, and as these contain only multiplication operations, it is simple and we can put the expression as follows:

$$\frac{4}{3}\left\{\frac{5}{8}+\frac{7}{48}\times\frac{25}{16}\times\frac{1}{2}\right\}$$

The remaining steps are obvious and can be easily followed. The product of 7-48 × 25-16 × 1-2 is added to 5-8, and the resulting sum is multiplied by 4-3, the final result being 1135-1152. This is the numerator of our compound fraction reduced to its lowest form.

$$\frac{4}{3}\left\{\frac{5}{8}+\frac{175}{1536}\right\}$$

$$\frac{4}{3}\left\{\frac{960+175}{1536}\right\}$$

$$\frac{4}{3}\times\frac{1135}{1536}=\frac{1135}{1152}$$

The denominator is also a compound fraction and must be simplified completely to obtain a solution. Thus:

$$\frac{\frac{4}{5}+\frac{3}{8}+\frac{1}{2}+\frac{3}{4}}{\frac{32+15+20+15}{40}}$$

$$\frac{16+7}{24+32}=\frac{64+21}{96}=\frac{85}{96}$$

making 82-40 as the numerator, and 85-96 as the denominator of the divisor of the whole fraction. Our sum now appears like this:

$$\frac{\frac{1135}{1152}}{\frac{\frac{82}{40}}{\frac{85}{96}}}=\frac{\frac{1135}{1152}}{\frac{82}{40}\times\frac{96}{85}}=\frac{\frac{1135}{1152}}{\frac{984}{425}}$$

We can now simplify and solve the whole sum without difficulty.

$$\frac{1135}{1152}\times\frac{425}{984}=\frac{482375}{1,113,568}$$

This final result cannot be reduced.

The foregoing example should suffice to show how to go about the solution of any fraction. It is merely a matter of remembering the rules. First of all, bring every expression to its lowest possible form. Simply the expressions contained in brackets, starting with the innermost. Remember that two terms connected with the sign of multiplication must be solved before those connected by any other sign. Take the expressions on top of the line dividing denominator and numerator first, and simplify them. In fractions such as we have just illustrated, the line dividing denominator and numerator is always made heavy, so that no mistake can be made.

If there is anything not clear to the reader in this subject, the writer will be glad to further explain it.

Decimal Fractions

Decimals are much more commonly used than vulgar fractions on account of their convenience, and simplicity. Multiplication and division of decimals can be effected by merely moving the decimal point to right or left in many cases. A whole number can be divided into any number of divisions by vulgar fractions, but with the decimal fraction, the number of divisions can only be ten, or multiples of 10, that is tenths, hundredths, thousandths and so on.

To signify a decimal fraction, a small dot, called the point, is placed before the first figure of the fraction. Thus: .1, .01, .001, etc. Following the decimal point the figures read to the right in descending value, just as in ordinary numbers they ascend in value, reading to the left. For instance, in the numeral 1234, the figure 4 on the right is a unit number. The next, figure 3, has ten times the unit value, that is, it is read as 30, the two figures together reading thirty and four, or thirty four. The next figure has 100 times the unit value, and the first figure 1000 times. Now if we place a decimal point after the last figure and set the same figures down again, we will get 1234.1234. The first figure will represent one-tenth part, the second figure 2 one-hundredth parts, the third figure 3 one thousandth parts, and the last figure four ten thousandth parts. Expressed in words, the number would be one thousand two hundred and thirty four, and one thousand two hundred and thirty-four ten thousandths. Expressed as a whole number and a vulgar fraction it would be $1234\frac{1234}{10000}$.

From this we can follow out the rule for decimals. A decimal we have seen is a 1-10th part. Now instead of writing it in fractional form, as 1-10, we write it .1. The point conveys the meaning that the figure following it is the numerator of a fraction having 10 as its denominator. If we wish to write 1-100 we prefix a cipher to the numerator, thus .01, which means that the denominator of the fraction is 100, the numerator still being 1. The addition of a second cipher as .001 means that the denominator is 1000, and so on, each cipher in the numerator adding a cipher to the denominator. Thus $\frac{1}{1,000,000}$ will be written .000001. The denominator is always understood, but need not be written, and never is.

Decimal fractions can be added, subtracted, multiplied and divided, and the operations are performed much easier than with ordinary fractions.

Addition of Decimals

In order to add together decimal fractions, all that is necessary is to set them down as one would any ordinary sum in addition, care being taken to keep them in their correct relative position to the point. For instance, in add-

ing .5 to .05, the figures must be set down thus:

.5
.05

and the addition then performed in the ordinary way. That is .5 + .05 = .55. This really means that to $\frac{5}{10}$ has been added with fractions: $\frac{5}{100}$, the result being $\frac{55}{100}$. Try this with fractions

$$\frac{5}{10} + \frac{5}{100} = \frac{50+5}{100} = \frac{55}{100}$$

Again add .345 to .123. We get

.345
.123
.468

Now take .75 + .25. This is

.75
.25
1.00

Here we have a sum which gives a whole number. Whenever the sum of the two first figures is more than 9, then the unit figure is set down and ten carried over, as in the ordinary way, but to the left of the decimal point. Let us take some whole numbers and decimals, to illustrate this point. Take 2.75 + .5. We have 2.75

.5
3.25

or again 1.25 + 2.75 = 1.25 + 2.75 = 4.00

Another example: 2.34 + 1.25 + 2.68 = 2.34
1.25
2.68
6.27

Add 2.3456, .0031, 1.002, 4.106, 5.00005. We have 2.3456
.0031
1.0020
4.1060
5.00005
12.45675

Subtraction of decimals is performed in the same way. The figures are set down with due regard to the place of the decimal point and subtraction performed just as with whole numbers.

Thus .123 — .016.

We have .123
.016
.107

Or 2.345 — 1.203
2.345
1.203
1.142

Subtract 346.007 from 458.0103
458.0103
346.007
112.0033

Subtract 369.0035 from 461.0045
461.0045
369.0035
.92.0010

The result of this would be written 92.001, the cipher at the end being left off. A cipher after the last significant figure in a decimal means nothing, but a cipher before a significant figure alters its value by ten times. This must be carefully remembered. Thus .1000 is only .1, or $\frac{1}{10}$, but .001 is not $\frac{1}{1}$, but $\frac{1}{10000}$.

Multiplication of Decimals

In multiplying decimals the same rules apply as in ordinary multiplication, the only precaution necessary being the placing of the decimal point in its correct position in the product. The sum to be multiplied is set down in the ordinary way, and after the multiplication is performed, the position of the decimal point is determined by counting the number of figures after the decimal point in both multiplier and multiplican. This can easily be understood from an example.

Multiply .25 by .75.
.25
.75
125
175
.1875

There are two figures in the multiplier after the decimal point, and two in the multiplicand, making four altogether. Then count from the right to the left four figures, and place the decimal point before the fourth figure. There are one or two points to watch in multiplication of decimals, which are very simple, but have a large effect on the result if not observed.

Take .555×.004
.555
.004
2220

Here we have only four figures in the product, and six figures after the decimal point in the multiplier and multiplicand. We must therefore add enough ciphers to the left of the first figure to make up the necessary number. We then have .002220. However we have already said that the cipher at the right hand has no value, so we can leave it off, and the product is .00222. The important point to remember is, do not take off any ciphers at the right hand end until the decimal point is fixed. They must be counted in when finding the place to put the point. Supposing the cipher had been cancelled before fixing the decimal point, the product would have been:

.555
.004
2220,

and taking away the cipher at the right, and adding the necessary ones to the left would have made .000222 instead of .00222. This would have made the product $\frac{222}{1,000,000}$ instead of $\frac{222}{100,000}$ It is easy to see the importance of this point.

That is all there is to multiplication of decimals. A few more examples will be sufficient to make it quite clear.

Take 2.789×1.234:
2.789
1.234
11156
8367
5578
2789
3.441626

Now unless great accuracy is required, there is little use in carrying the decimal places more than four figures from the point so we would eliminate the last two figures, and make the answer 3.4416. Leaving out the last two figures makes an error of $\frac{26}{1,000,000}$ which is not very serious.

Multiply .0078 by 2.25
2.25
.0078
1800
1575
.017550 say .01755

Mutliply 6.25 by 25.75
25.75
6.25
13875
5150
15450
161.0375

Division of Decimals

When we come to the division of decimals we find it just as simple. To divide decimals, proceed in the ordinary manner, except that there must be as many figures after the decimal point in the divisor as in the dividend. The position of the decimal point in the quotient is

determined in a somewhat different manner than has been used for the other operations. Take a simple case. Divide .4 by .2, we have .2).4(.2. Now the answer is two whole numbers, not .2 or any fraction. How is this result arrived at? Well, let us try it another way $\frac{4}{10} \div \frac{2}{10} = \frac{4}{10} \times \frac{10}{2} = \frac{40}{20} = 2$. It means simply that 2 tenths are contained in 4 tenths twice. Now let us divide .2 into 4. Here we have one figure after the decimal point in the divisor, but no decimal point in the dividend. We must add a decimal point and a cipher and we then have .2 divided into 4.0. Now we may neglect the decimal points altogether and simply make our sum 2)40(20. Let us now reverse this sum and make it 4 divided into .2. Here we have a figure after the decimal in the dividend, and none in the divisor. We must add a cipher and a decimal point to the divisor. We then have 4.0 divided into .2. Again leaving the points out now that the number of figures following them is the same, we get 40)2. This of course will not go. What must be done to make it possible? The first thing to do is to put a decimal point in the quotient, at the same time adding a cipher to the dividend, thus: 40)20(. Still 40 will not go into 20. We add another cipher to the dividend and a cipher in the quotient. We now have 40)200(.0 This will now go 5 times and we have 40)200(.05 the answer

```
200
---
...
---
```

being .05. Let us try this out by fractions just to show it is correct. We will have $\frac{2}{10} \div 4 = \frac{2}{10} \times \frac{1}{4} = \frac{2}{40} = \frac{1}{20}$. Now $.05 = \frac{5}{100} = \frac{1}{20}$.

Suppose we have to divide 2.25 by 1.005. We have one figure more after the decimal point in the divisor than in the dividend so we must add a cipher to make them even, making the statement 2.250÷1.005. Then proceed as in ordinary division leaving out the decimal points:

```
1005)2250(2
     2010
     ----
      240
```

We have a remainder. In order to proceed we must place a decimal point after the 2 in the quotient, and add a cipher to the remainder and then go ahead.

```
1005)2250(2.2
     2010
     ----
      2400
      2010
      ----
       .390
```

Add a cipher to this remainder and divide again

```
1005)2250(2.23
     2010
     ----
      2400

          ----
           975
```

There are some cases known as recurring decimals, or repeating decimals which occur in division. This means that it is impossible to ever reach an even quotient without a remainder. For instance $100 \div 3$ gives $3)100.00000$ ——— and 33.33333 so on for ever. In these cases the recurring figure is set down with a small dot on top and this shows that it is repeating.

In the case of a decimal fraction of 4 or more figures, it is quite easy to shorten it without affecting the accuracy to any material extent. Of course, it must be understood, that sometimes accuracy to seventh place is necessary, but one can always judge when a statement can be shortened for the sake of simplicity. Take a fraction like .4985. This can be made .5, the error being only .0015 or $\frac{15}{10{,}000}$, which is negligible in most cases.

If the fraction were .428 it could be made .43, and so on.

We have shown that a decimal fraction is easily convertible to a vulgar fraction. The reverse is the case also. To convert a vulgar fraction to a decimal fraction, the denominator is divided into the numerator. For example, to convert ¾ into a decimal fraction:

```
4)30(.75
  28
  --
   20
   20
   --
   ...
   ---
```

Four will not go into 3, so a cipher is added to the dividend, and a decimal point in the quotient, division then proceeding in the ordinary way. Convert 3-64 to a decimal.

```
64)300(.046875
   256
   ---
    440
    384
    ---
     560
     512
     ---
      480
      448
      ---
       320
       320
       ---
       ...
       ---
```

Convert 15-16 to a decimal

```
16)150(.9375
   144
   ---
    60
    48
    --
    120
    112
    ---
     80
     80
     --
     ..
     --
```

Convert .825 to a vulgar fraction

$$\frac{875}{1000} = \frac{175}{200} = \frac{35}{40} = \frac{7}{8}$$

Convert .875 to a vulgar fraction

$$\frac{875}{1000} = \frac{175}{200} = \frac{35}{40} = \frac{7}{8}$$

The Theory and Practice of Electricity

In These Articles the Theory Will be Developed Sufficiently to Enable the Practical Man to Grasp the Underlying Principles of Apparatus Under His Care, Both Direct Current and Alternating

W. F. SUTHERLAND

THE greater portion of the electrical industry of to-day has been built up around the use of electricity in the transmission of energy. Its use is only a means to an end and makes possible the development of waterpower and their use in furnishing cheap power to industries in towns and cities remote from the waterpowers themselves.

Other means of transmitting power are used and examples will occur to any one, compressed air, steam and hydraulic systems are all used to advantage under certain conditions.

In all of these as in electrical engineering three things are essential, means for generating power, means for its transmission and means for its utilization. The air compressor changes the physical state of the air being worked upon and in so doing does work upon it thus storing up energy in it. The pipe line merely serves to convey this air to the point where it is to be used and at the end of the line where the air-drill or other machine is located, the air is allowed to expand and in doing so gives out energy.

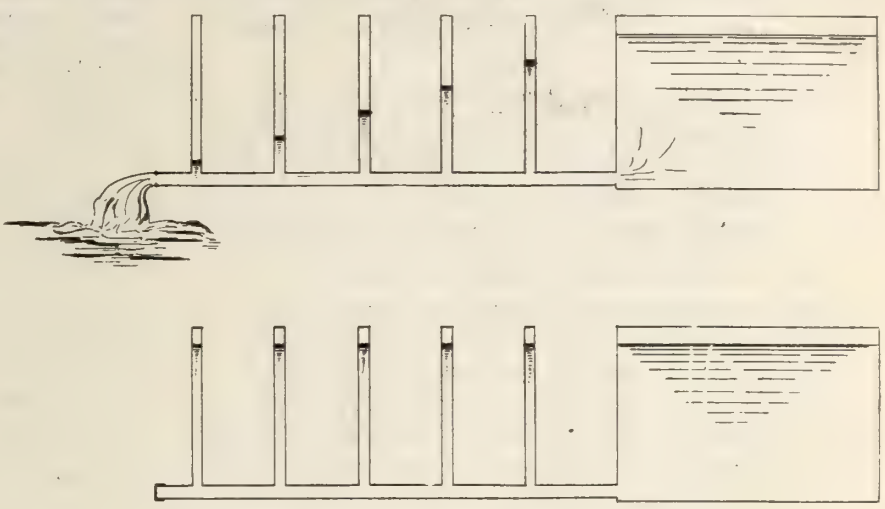
In the steam boiler energy in the form of the heat given off by burning fuel serves to increase the energy of the water evaporated for every pound of steam contains considerably more energy than the water from which it was made. The pipe-line here too serves merely as a means of conveying the steam from one place to another and in the engine by expansion the steam gives out some of its energy, its pressure being lowered and some of it being converted back into water.

With a hydraulic power installation such as seen at Niagara Falls a different form of energy is employed, that due to the elevation of a body of water over a lower pool. A hydraulic power plant makes use of potential energy the same form that is stored in a weight on a table by viture of its height from the floor.

Since the flow of water is relatively simpler than the flow of either steam or air and since many of the facts relating to it can be usefully used in the study of electrical phenomena it will be well to devote a little time to its study and to reason out some of the facts relating to it.

In Fig. 2 we have a reservoir or tank filled with water and having a pipe leading away from it near the bottom. This pipe is shown closed and five vertical pipes or glass tubes can be imagined opening into it. If as supposed the cap in place on the end the water will stand in all the tubes at the same level and at the level of the water in the tank.

If now the cap be removed and water permitted to flow out a change will be observed in the level of the water in each of the tubes. That nearest the tank will drop slightly that next to it, more so, and so on until the last tube is inspected when it will be seen that the water level in it is very little if any above the level of the horizontal tube itself.



HEAD OF WATER STILL AND FLOWING.

The height of the top of the water in the tank over that in the reservoir below is called the head. This is only another name for pressure and it is seen that while this head or pressure is uniform in the tube while no water is flowing, it changes with the distance away from the reservoir when a flow is established. It is of interest to find out how this loss of head is used up and it may be briefly stated that the major portion of it is used up in doing work on the walls of the tube. When the water flows through the tube friction is set up between it and the tube. This friction uses up energy and the result is seen in the generation of heat.

In Fig. 4 a diagrammatic view of a power plant is given with a dam and impounded water behind it, a penstock, turbine and powerhouse. From the pen-stock glass water gauges may be imagined much as shown in the picture. When the turbine gates are shut off the water in all of these would rise to the level of that behind the dam but when the turbine is running these levels would drop much as shown in the diagram. In this case the pressure due to the total head, or height between the dam and the tail race below the power house, is not all used up in overcoming friction but only a small portion of it as shown by the empty portion below the top of the gauge tube.

That is of the total energy available a certain amount is used up in overcoming friction throughout the system while the remainder does useful work in rotating the moving element of the generator.

In obtaining data on the flow of water and its relation to the power which can be developed from the flow three things must be taken into consideration, the quantity of water, the time in which it flows and the pressure or head under which it flows. The first two of these give the rate of flow, thus when we speak of gallons per minute we are dealing with a compound unit which simply means that a certain number of gallons or a definite quantity of water will flow, possibly through a pipe, in one minute.

If a stream has a flow of say 1,000 cubic feet per minute and in going over a fall has a drop of 100 ft. we can figure the amount of power available from its use. One cubic foot of water weighs 62½ lbs. and 1,000 would weigh 62,500 lbs. In falling 100 ft. energy would be available and work could be done to the extent of $62{,}500 \times 100 = 6{,}250{,}000$ ft. pounds. This is equal to $6{,}250{,}000 \div 33{,}000 = 189$ horse-power nearly.

In electrical engineering we have a number of similar quantities although in this case we are measuring energy directly and not physical substances such as water. We have a unit of quantity since a certain definite amount of electrcity will always produce the same effect, we have a unit denoting rate of flow on the quantity flowing in unit time and we have another unit by which we measure what may be termed electrical head or pressure causing flow. There are also names given to the power or capacity of a generator or other machine for doing work and finally a unit by which the amount of work can be done.

The Unit of Quantity

Unlike material things, electrical energy cannot be measured directly. We cannot speak of it in terms of cubic feet, pounds or gallons, but it can be measured by the effects produced by its presence or flow, and in this respect it is like all other forms of energy.

A definite amount of electrical energy will always produce the same effect or do the same amount of work under the same conditions and this renders it easy to define a unit of quantity measurement.

To the unit denoting quantity the name of coulomb is given after one of the famous electrical physicists who was responsible

Varieties of Prime Movers

THERE are described in this issue of POWER HOUSE two widely different types of prime mover, while an article sent in by a contributor deals with the operation of an auxiliary to a third type. There is a great difference now to the days not so very far past when a stationary engineer was called upon to deal with either one of two types of engine, the slow speed Corliss of the high-speed automatic. Nowadays the prime mover may be any one of several types of turbines, a Diesel or Semi-Diesel engine, a gas engine with its own gas producer, high speed direct connected engines of the vertical or horizontal enclosed type, or the heavy duty Corliss type, or some one of its variations, such as those with poppet valves, or the more common gridiron valves.

It is hardly possible for any man to have a practical acquaintance with all these various types of prime movers, but there is nothing to prevent him being acquainted with their general principles and operating features. He is then in such a position that with a short actual experience of handling, he will become familiar with their characteristics. The man who knows how a machine should function, and the principle of its design, is in a better position to get results, even though inexperienced, than he who knows the apparatus from an operating view point alone. It all comes down to the same old point. Eternal study is the price of competence in these days of engineering development.

Hydraulic Testing

NOTWITHSTANDING all that has been written and spoken from time to time on the purposes and functions of the hydraulic test as applied to boilers, it would seem as though there was still a widespread misunderstanding as to these important matters. There are frequent enquiries coming into this office, asking our advice as to what percentage of the hydraulic test pressure should be allowed as the working pressure, and in conversation with a gentleman who has had wide experience all over the country, we find that there are still many men who entertain very hazy notions as to the purpose of the hydrostatic test.

Personally we believe that many unexplained failures and explosions of boilers could be traced back to an unwise application of hydraulic pressure and we believe that there is no greater potential source of damage than by the injudicious application of high water pressure. The purpose of the hydrostatic test is purely to determine the excellence or otherwise of the workmanship, and to show up any weakness in the material or design that may have escaped notice up till that time. The hydraulic test pressure is based on the safe working pressure of the boiler as found by calculation of the various parts of the shell, heads, stays, joints, furnaces, combustion chambers, etc., according to the type of boiler. The ultimate strength of the whole boiler is determined by the ultimate strength of its weakest part, and the safe working pressure is determined by taking a factor of safety found by experience to be suitable to various conditions, and dividing it into the previously determined ultimate bursting pressure. This factor of safety varies from 4 to 6, according to the type of boiler and the workmanship put into it, or if preferred, the methods of manufacture. The hydraulic test pressure is from 1½ to 2 times the safe working pressure as found by calculation, when the boiler is new. Supposing we have a new boiler, built of plates with a tensile strength of 60,000 pounds per square inch. The factor of safety we will say is 5, which allows a safe working stress of 12,000 pounds per square inch. The initial hydraulic test will be then 24,000 pounds per square inch, which will be well in the elastic limit of the material. Generally speaking, the limit of elasticity is reached at about one-half or slightly more than half the ultimate breaking stress. In plain language the limit of elasticity means that point at which the metal ceases to return to its original form after stressing. When a boiler is new, the metal of which it is built is ductile, and possesses resiliency. That it, although it may be distorted by high pressure, as long as that pressure is under the elastic limit of the material, it will resume its form. After being in service some time, the metal loses some of this elasticity. It tends to crystalize or becomes brittle, and acts exactly the same as an elastic band which has been used so often that it eventually becomes as inert as a piece of string. If you try to stretch this old elastic band over the bundle of papers it originally covered, it will break. This loss of elasticity in the metal of a boiler, is of course a long and slow process, unless the conditions are very favorable to it, such as occur in careless operation. Suppose the boiler we have just been considering has been in service ten years, and has had reasonable usage during that time. It will probably be found on inspection to be free from corrosion internally and externally, clean, and free from leaks. The inspector will take all these facts into consideration, and allowing the same working pressure, will probably test to 1½ times that pressure, to make sure everything is tight, and there are no weaknesses that he has overlooked. That means that the stress on the plates will be 18,000 pounds per square inch, considerably below the original elastic limit of 30,000 pounds. Here the hydraulic test has been used in a perfectly proper and safe manner. Now suppose that the very same boiler has been working for ten years, and has been subjected to careless operation, and general neglect which sometimes happens, or perhaps we should

say too often happens. Careful examination would show that the condition of the boiler was such that the factor of safety should be raised to probably 8 which would reduce the safe working stress on the plates to 7,500 pounds per square inch. The hydraulic test pressure would then be such as to put a stress of only 11,250 pounds per square inch on the metal. This is only a little over one-third of the original elastic limit, and leaves an ample margin of safety. On the other hand suppose an exponent of the hydraulic test, pure and simple comes along, and after enquiring what the working pressure of the boiler is from anyone he sees around, proceeds to apply it without any further thought. This is not a wild exaggeration, because this very thing has occurred many times both in Quebec and Ontario, and probably in other parts of Canada also. The working pressure as originally found, was, say 150 pounds per square inch, and as the owner wishes to continue at this pressure, a test pressure of 300 pounds per square inch is decided upon. Now this is what happens. We have just seen that owing to the condition of the boiler, the factor of safety should be raised, or in other words, the working pressure reduced. The original factor of safety of 5 gave a working pressure of 150 pounds, therefore the new factor of safety of 8 will allow a working pressure of only 94 pounds. The hydraulic pressure of 300 pounds to the square inch is over three times the allowable working pressure as determined by actual examination. This is bad enough, but what happens to the elastic limit of the metal? It is safe to say that if the material has deteriorated sufficiently to make a large reduction in working pressure necessary, the elastic limit has correspondingly decreased. In putting a pressure of double the original working pressure on the boiler, the original elastic limit is nearly reached. If the elasticity has decreased only 10 per cent. the boiler is stressed very nearly to its present limit, while if it has decreased much more, the elastic limit is passed. This may not be discernible, but the fact remains that the boiler is left in such a condition that the slightest shock may result in a failure of the metal, and this shock might be only the sudden opening of a valve, or even the sudden release of pressure due to the safety valve opening. After a test of this kind on an old boiler, without previous examination, and no allowance of any kind being made for age or condition of the material, anything may happen, and not infrequently does. The unfortunate part of this indiscriminate use of the hydraulic test is that it is too often resorted to by those who ought to know better, and the results accepted as satisfactory by those most immediately concerned. There is no excuse at this time and date for anyone to be ignorant of these most important facts, and it should be made an indictable offence for anyone to put an hydraulic test on a boiler before previously ascertaining all the particulars and condition of the boiler, and basing the test pressure on the results of this investigation. Basing working pressure on hydrostatic pressure is turning things topsy-turvy with a vengeance.

Cheapening Propulsion

THE progress that has been made in increasing the efficiency of ship propulsion, is well pointed out in connection with the launching of the Cunarder Scythia, at the yards of Messrs. Vickers, Ltd.

The old Scythia, which was in use in 1875, required 17 pounds of coal to move 100 tons of cargo one mile, whereas the new vessel burns only four pounds of coal or three pounds of oil while conveying the same weight at the same speed for the same distance.

Sir James McKechnie, of Vickers, speaking at the launching, made it plain that he did not consider that the last improvement had been made. He looked to see the internal combustion engine used in large sea-going vessels, and cut the fuel consumption to 1½ pounds of oil per 100 ton miles at the speed of the old Scythia.

The great difference between the new Scythia and the one of 45 years ago, has been made possible by the greater size of the ship, the increased efficiency of high-pressure steam, and then by the geared turbine, which is giving greater efficiency than the former practice of direct connection between the turbine and propeller shaft.

If Sir James McKechnie is right—and it will take some considerable proving to show that he is not—it means that the internal combusion type of marine engine is destined to effect a saving of millions of tons of fuel every year.

Not So Eager To Join

AN attempt by John Fitzpatrick to organize the steel workers in the South Chicago district met with poor success in a meeting which he called recently. A year ago, before the steel strike, Lincoln Hall, Ninety-first Street and Commercial Avenue, South Chicago, was crowded with more than 2,000 enthusiastic workers. All joined the union.

On May 13 only 150 gathered there, although handbills had been distributed among 25,000 workmen. The bills announced that the meeting had been called by the National Organizing Committee of the Iron and Steel Workers of America. It was also stated that a succession of weekly gatherings would be held until the union included every man working in a steel plant in the district.

The steel workers have been tinkered with too much already. If sanity has returned to the point where the appearance of such men as Fitzpatrick and Foster get nothing but an indifferent reception—then so much the better for the steel trade.

Some Common Sense Needed

THE price deflation that has struck many lines in the States has not yet reached the industries of Canada, and as far as many of the lines go, particularly iron, steel, or anything in these classes, the move is not likely to be generally effective.

The market is too empty to permit of much price deflation.

At the same time the trade ought to bear in mind that very serious thought should be given before deciding on more advances.

Unfortunately, there are some lines where the feeling seems to be yet maintained that "we had better get in on this good thing while it lasts."

Reasonable profits should still be the standard of business, rather than maximum exactions.

Firms that are building for the future are well advised if they consider the service they can give to their customers, rather than the money they can wring out of them.

Don't be devoured with over anxiety lest some of the new taxation shall hit you, and that you shall not be able to pass it all along to the next man down in the line toward the ultimate consumer.

If you have an honest case, where your costs and expenses have gone to the point where you must increase, do so openly and honestly.

If you can still do business at present prices, then keep out of the procession leading toward higher costs.

Business is at a point now where a little encouragement and added stability means a great deal. There are projects held in abeyance, because those behind them will not go forward if they think that costs are going to continue upward.

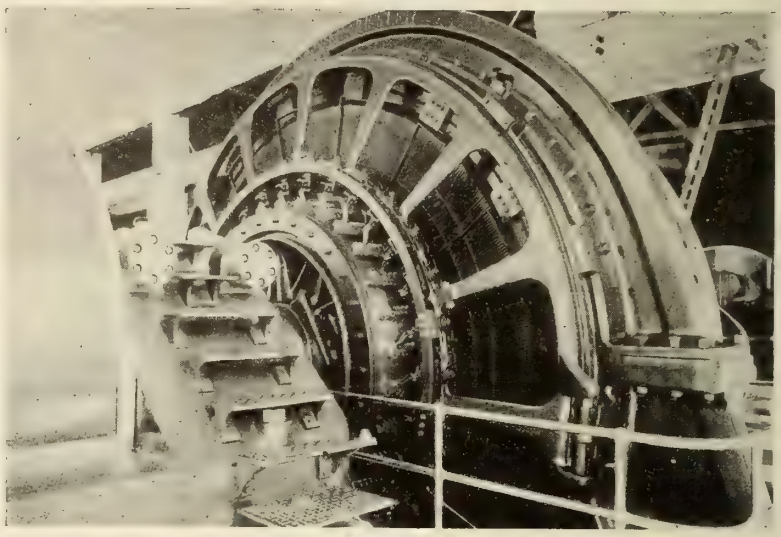
The beating down of all talk of depression and falling-off in trade rests in part with those who are in business themselves.

Progress in New Equipment

The Trueing of Commutators

An Article Descriptive of a New Type of Commutator Grinder Which Possesses Many Features of Interest

By W. F. Sutherland



IN the November 5 issue of POWER HOUSE an article appeared descriptive of various methods of commutator resurfacing. This present article presents some additional material of interest bearing on the same subject.

War activities were responsible for many new devices in almost all lines of mechanical endeavor, and it is interesting to note that the submarine, developed to such a high state of perfection, was responsible for the invention of a new commutator grinder for machines of large size. The grinder illustrated and described herewith was adopted by the United States Navy in all yards and on repair ships after exhaustive tests. For work of this nature, and particularly on the larger sizes of commutators, a machine possessing considerable rigidity and a wide adaptability is desired and the Shafer-Decker Co., Rochester, have given considerable attention to these details.

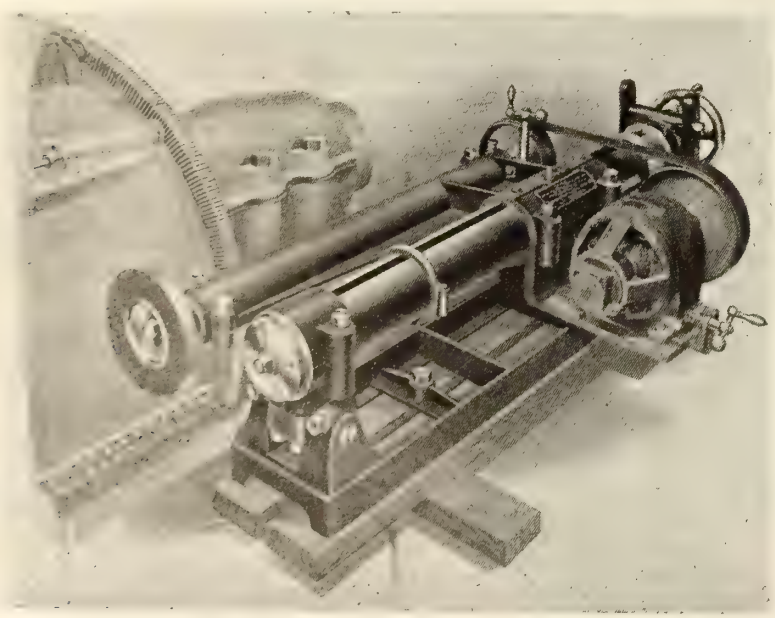


FIG. 1—GENERAL VIEW OF GRINDER IN POSITION.

For satisfactory results the commutator to be trued up should revolve at its normal speed, thus taking care of strains resulting from centrifugal force. The commutator, when thus trued up, will run truly circular at its operating speed, even it it should be out of round when at rest.

The cutting and grinding wheels used should be of a special character and combination of materials. Those used by this firm are entirely free from clogging with particles of copper or mica. The wheels are perfectly balanced and operate at a peripheral speed of about 6,000 feet per minute. A coarse wheel is used for cutting irregular commutators to a true surface and a fine wheel for final finishing.

The skilled mechanic will realize that there is needed a nicety of adjustment and sensitiveness of touch for working at the same time on two such vitally different substances as soft copper and hard mica. Every precise adjustment, direct, vertical, horizontal or longitudinal, is available by reason of the general design of this machine, of which a good conception may be gained through the inspection of the accompanying engravings.

The grinding wheel shaft is supported in a hollow casting provided with coned bearings at each end. It is driven by means of a belt from a motor on the op-

posite side of the supporting arm upon which the whole rotating mechanism is carried. This arm is pivoted in two planes at one end so that it can be swung through a small arc in a vertical plane for levelling and through a similar arc in a horizontal plane for lining up.

The feeding of the wheel into the work is accomplished by means of a supporting sleeve with eccentrically placed bearings supporting the sleeve. This sleeve is rotated by means of the worm wheel (89) shown in the line drawing.

The wheel with its drive motor is fed along the face of the commutator by means of the wheel 46 and the feed screw which engages in a nut on the wheel carriage. The feed screw moves the carriage with motor and driven pulley, including the driven shaft which carries the grinding wheel along the tubular sleeve. The distance of travel is thirty inches.

In setting up the grinder one complete brush holder with its brushes is removed at the position of the horizontal diameter where the grinding wheel is to be applied. All other brushes are raised from the commutator. Having marked

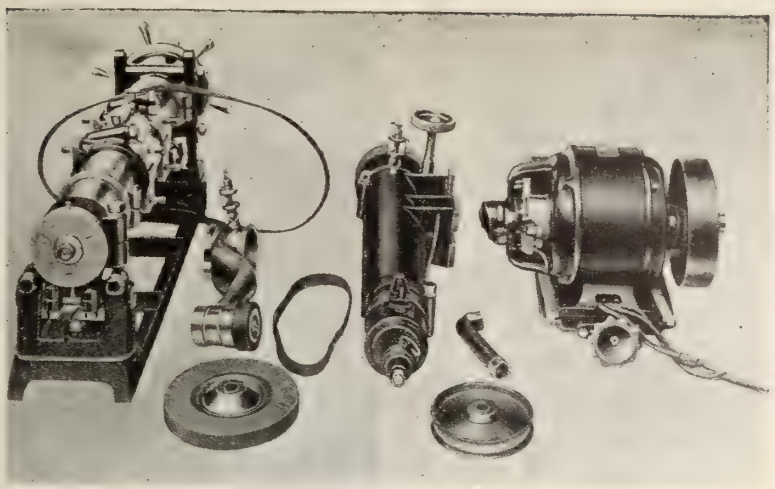

FIG. 2—VIEW OF NAVAL GRINDER PARTLY KNOCKED DOWN.

position the carriage is then moved to the extreme inward position with the grinding wheel as near to the risers as can be safely operated, and the stop ring is set for this position, then, by the use of inside calipers or micrometers between the commutator and straight edge

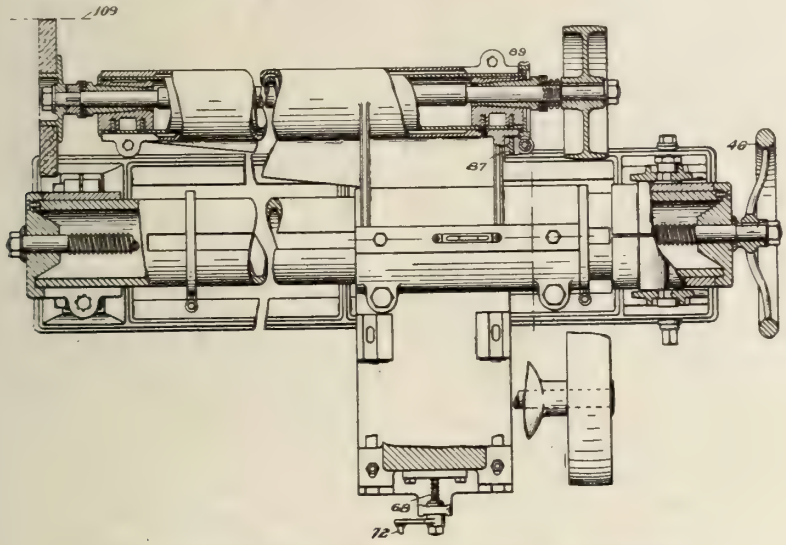

FIG. 3—PLAN VIEW OF GRINDER PARTLY IN SECTION.

the lines of horizontal diameters of the commutators to be treated, the surface grinding machine is securely mounted on substantial blocking to such an elevation as will permit the application of the grinding wheel at the correct location of horizontal diameters and also allow freedom of horizontal travel of the grinding wheel from end to end of the commutator.

A good way to set up the blocking is to clamp the 3 by 6 timbers of sufficient length on each side of the pedestal at commutator end of generator or motor and bolt these firmly in position. To these can be bolted two shorter timbers extending for the length of the commutator inward toward the fields. These timbers to be of sufficient outboard length to receive and support the surface grinder. All this set up blocking requires is to be securely bolted to avoid slipping from position during grinding operations.

After the device is clamped firmly in on spindle barrel, the machine can be brought in exact parallel position with the commutator by adjustment of a hand screw after the grinding wheel has been run back to the extreme position of grinding at opposite end and the stop ring set; the wheel can then be adjusted to the commutator by turning the hand wheel No. 87 for such a cut as will demand three to four amps. on the motor circuits; at no time should the cut of the grinding wheel be such as to exceed 4 amps' draw on the motor circuit.

After the machine has been set up the armature should be slowly turned and a straightedge used to find and mark all the high and irregular spots on the commutator. When these are determined the grinder wheel should be adjusted to first take these down.

The coarse wheel should be used for first or rough grinding, and gentle, moderate cuts are much to be preferred to heavy ones. The armature is rotated at full speed and the grinding wheel should also be driven at the correct number of revolutions per minute.

When a true, accurate circumference and face are obtained on the commutator the coarse grinding wheel is removed and the fine one substituted for finishing the surface. The work, by this means, can be performed with such skill and accuracy as to secure a finish superior to that usually given to commutators on new generators or motors.

No definite time is given by the makers for the refinishing of commutators. It is obvious that when new com-

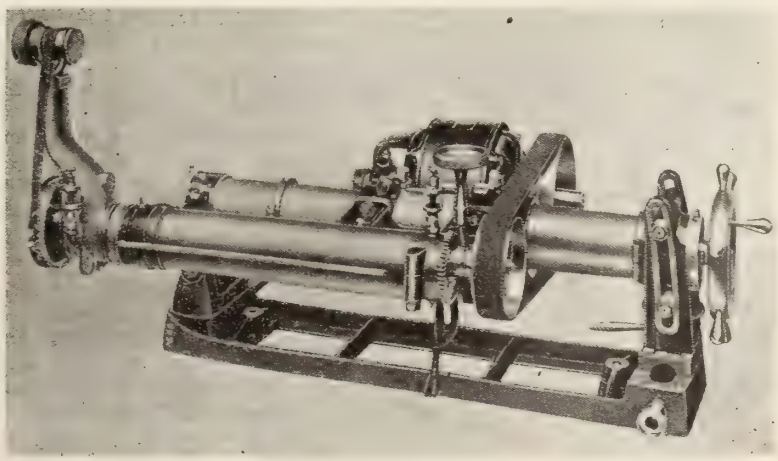

FIG. 4—GRINDER WITH EXTENSION ARM.

mutator bars are set in an old commutator these must be dressed down by filing or otherwise to the surface of the commutator. This requires time, and where a commutator is seriously grooved or seriously out of true, a considerable amount of copper and mica must be cut away to dress the high and irregular parts down to the true surface. According to conditions these jobs have taken from 4 to 60 hours.

This grinder is made in a naval type also for use on board ship, where lightness and extreme portability are desired. This latter type of machine weighs 325 pounds, and resurfaces commutators up to 16 in. in length.

The A. R. Williams Machinery Co., Ltd., are Canadian agents for this machine.

WATER LEVEL INDICATOR FOR BOILERS

The ordinary method of checking the water level in a steam boiler by means of test cocks has the disadvantage that with such pressures as are now in use the fluid issuing from the cocks, when they are open,, is in the form of a jet which is practically the same whether the water level be above, or below, the test cock. Partly in view of this it has

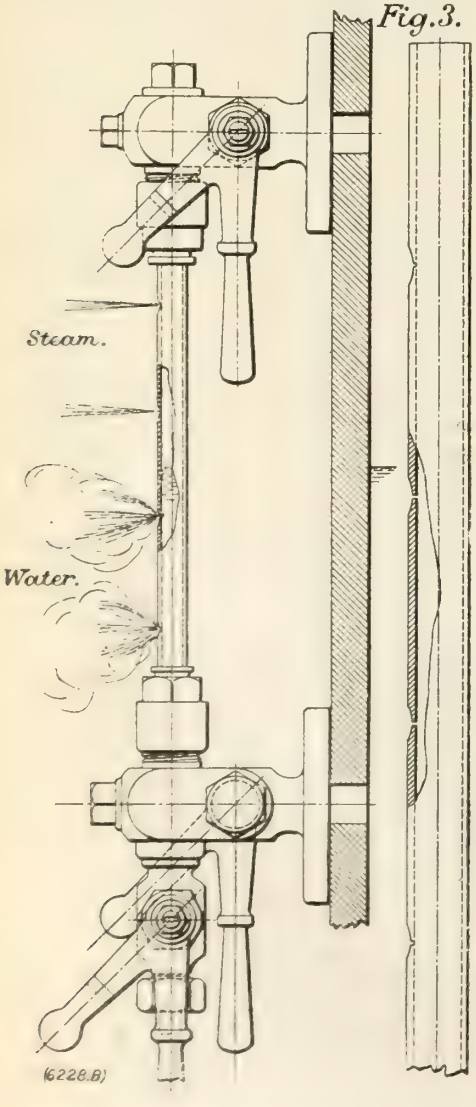

Fig.3.

long been usual in good practice to fit two water-level gauge glasses instead of one. Even so, however, it is possible that the two glasses may be out of action at once, and in some cases it is not always easy to distinguish between a full glass and an empty one. A simple and effective form of water-level indicator which has all the advantages of the test cocks in checking the water level, but does not suffer from their disadvantages, has been patented by Messrs. Cammell Laird and Co., Limited, and is being manufactured by Messrs. Bromel Patents Company, Limited, of 64, Darnley-street, Glasgow. It consists of a metal tube of external diameter and length such that it may replace the glass tube in any ordinary water gauge. The metal tube is drilled with a series of small holes about 1-32in. diameter, and at a pitch of a few inches apart.

When the tube is in position on a boiler and the gauge cocks are open so that it is put in communication with the water and steam spaces, it is found that the jets which issue from the holes which are below the water level are very distinct in character from those which issue from the holes above the water level. The steam jets issuing above the water level are barely visible and have a very small angle of divergence, while the jets below the water level are in the nature of a distinct white, cloudy spray, and have a wide angle of divergence. This is illustrated in Fig. 1 which shows an indicator in operation. It will be clear that this device enables a very close reading of the water level to be obtained with ease and certainty, and that there is nothing in it to go wrong. A hole may be stopped up, but if this happens it is at once evident and may easily be cleared. With the size of the holes used, 1-32in. diameter, this minor trouble is not very likely to occur. It is found that the best contrast between the jets is obtained when the length of the jet passage is equal to its diameter, and to obtain this proportion a flat is filed on the tube at the point where the hole is drilled. This is indicated in the general drawing, Fig. 2, and the detail of the tube, Fig. 3. It will be evident that these distinctive jets may be obtained by fitting suitable nozzles to ordinary test cocks, but the arrangement would not give the close reading of water level which is obtained with the indicator, unless an unusual and probably undesirable number of test cocks were fitted.

THEORY AND PRACTICE OF ELECTRICALS

Continued from Page 265

for the earlier advancement of the art. For practical purposes the coulomb has been defined as that quantity of electricity which when passed into an elecgro-plating solution will deposit 0.001118 grains of silver. This unit bears no relation to time for it does not matter how long it takes whether a minute or an hour. This unit the coulomb is exactly similar to others more familiar, the pound, the cubic foot, the ton except that it is a measure of a definite amount of energy and not of some physical thing.

It may be mentioned that the coulomb is very seldom used in electrical engineering under its own name but the idea of quantity is expressed by more familiar units as will be seen below.

The expression gallons per minute is a familiar one and its meaning is generally understood. A similar conception of flow is in use in electrical engineering but instead of saying so many units of quantity per second or per minute a name is given to the whole phrase and the rate of flow is called an ampere. Thus while we might speak of so many coulombs of electricity flowing during a period of one second we simply say that the current has a strength of so many amperes. This is a point which often confuses those beginning the study of electricity and it must always be remembered that the term amperes implies two distinct ideas that of quantity and that of time. It will further be of much assistance to remember that it is exactly analogous to gallons per minute or some similar expression.

The quantity of electricity conveyed by a current of one ampere flowing for the time of one second is called one amper—second (never one ampere per second) and is equal to one coulomb. Thus we might in an exactly similar manner say that the quantity of water conveyed by a current or flow of one gallon per second for one second is one gallon.

To make the meaning of the term ampere more definite and concise it may be well to dwell upon it a little longer. It may be asked why do we not say so many amperes per second? The answer is, as before mentioned, that the term ampere includes within itself the idea of time and instead of amperes per second the correct term would be coulombs per second. Coulombs per second and amperes mean exactly the same thing.

Amperes per second is a term which is analogous to saying feet per second per

second and when an expression such as this is used it expresses a change in velocity or acceleration. Later on when the study of alternating current is taken up it will be seen that amperes per second means the rate of increase or decrease in the current flowing and not the measurement of a steady rate of flow.

Unit of Pressure or Potential

We have seen in the hydraulic transmission of power that a certain element existed which was termed pressure or head and that it was this element which caused the flow of water from one reservoir to another. For if we had two small jars joined with a rubber tube entering at the bottom of each and filled them with water, we would find if the jars were placed on a level, flow of water from one to the other would cease when the water came to the same level in each. If one jar was lowered water would flow and the more it was lowered the faster would the water flow.

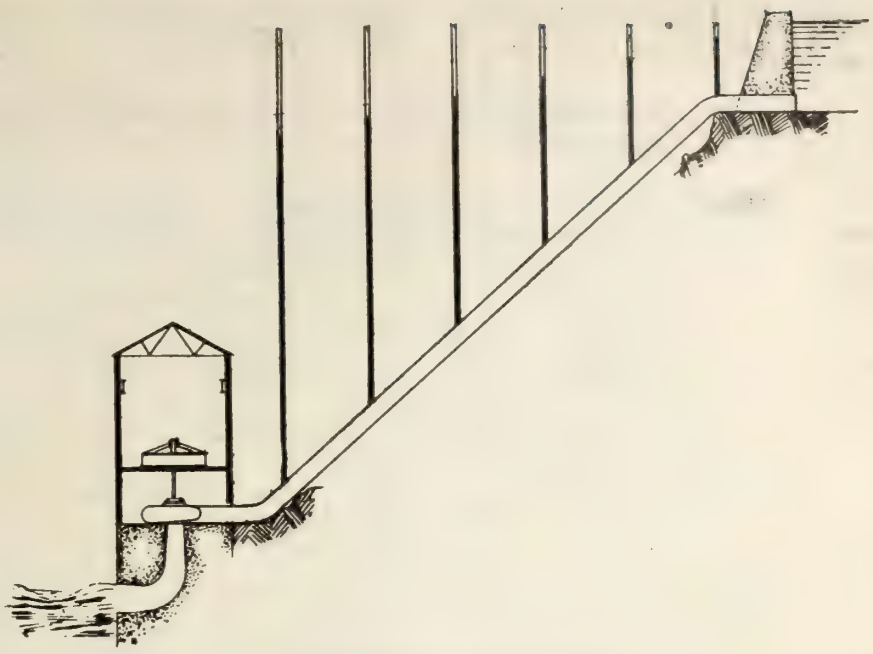
In like manner a similar quantity exists in electrical engineering and it is the electrical pressure which causes or tends to cause a flow to exist. Tends to cause, because the pressure can exist whether any current flows or not. In Fig. 4 the outlet is stopped by a cap and the pressure still exists and in fact is greater at the outlet than it was in Fig 3 where flow of water was permitted.

To the unit of electrical pressure the name of volt is given, after one of the earlier investigators into electricity "Volta". The word volt implies in electrical matters just what either so many feet head or pounds per sq. in. do in hydraulics.

In Fig. 5 we have a source of electrical pressure, the generator which takes the place of a dam on an elevation in hydraulic practice and we have also a line which is supposed to be grounded at the far end. The other generator lead is also grounded as are the bottom terminals of the volt-meters b, c, d and e. We have in this case used only one line so that the diagram shall be, as far as possible, similar to Figs. 2 and 3.

We can thus neglect the return circuit which is made through the earth. It must always be remembered however that an electrical circuit must be closed on itself and have neither beginning or end for the current which flows out must return. A hydraulic power plant has the same return system in effect although pretty well disguised, for water must be continually raised from the lower level to that of the dam above by the sun's energy. The water which finds its way to the oceans and lakes through the waterwheel is evaporated, forms clouds and these in turn through rain keep the reservoir full.

If we start the generator in Fig. 5 it will be noticed that the volt-meter e will register the greatest amount that next to it a smaller amount and so on until we come to b which will register scarcely anything at all. The indications of these instruments will correspond exactly to the height of the water in the gauges of Fig. 3. Volt-meter a will register the drop in head between the beginning and end of the line and its reading will correspond very nearly to that of meter e. This reading corresponds to the difference in the heights of the water in the right and left hand gauges of Fig. 3.



HYDRO-ELECTRIC POWER PLANT.

If the switch shown in Fig. 5 be opened we will have a similar case to that shown in Fig. 2. Where neither electricity or water will flow. All the meters B, C, D and E, will show the same valve which will be that of the generator causing current to flow. As in Fig. 2 where no difference exists in the level of the water in the gauges so in Fig. 5. gauge A will show no reading whatever.

From this similarity it may be argued that there is some property of the electric circuit which tends to impede the flow of current through it. This property is called the resistance of the circuit and is measured in a unit called the ohm. This resistance increases as the length of the circuit, decreases as the area of the conductor is made greater and varies with the different materials of which the conductor is composed

Those materials which offer a relatively low resistance, such as the metals are said to be conductors; while those which offer a relatively high resistance such as glass, rubber, dry paper, etc., are called insulators.

The Unit of Power

When speaking of engines, water-power and other apparatus the term horse-power is very commonly used. Electrical apparatus can be so rated and in the case of motors which deliver mechanical power this is done, but when speaking of generators, transformers and other apparatus the term is never used since it is more convenient to use another definite unit which is connected to the electrical units of pressure or potential and curent flow by a very simple relation.

When we speak of the power of a waterfall we have two things associated together in our minds, first, the amount of water flowing over it in a definite time interval and secondly the head or height of the fall. Likewise when the power generated by an electrical machine is considered we have to think of the amount of electrical energy it can generate in one second and secondly the pressure or voltage at which it is generated.

The amount of energy or the number of coulombs of electricity generated in one second is expressed simply by the one word ampere and the pressure by the number of volts. So we can say that the power generated will be equal to the product of the number of amperes flowing by the number of volts at which it is generated. To the unit of electrical power the word "Watt" is given and the following equation connects the three units Power equals current multiplied by voltage or Watts=amperes x volts.

Put a Farnsworth System to Work in Your Steam Plant

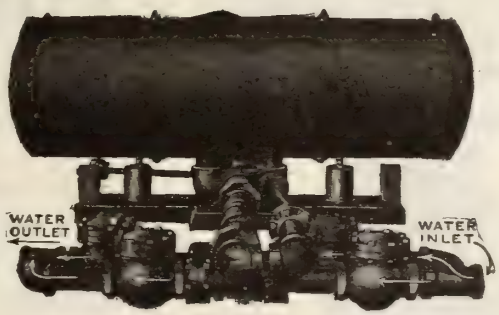
Farnsworth-equipped plants produce more steam with less fuel and less expense than other plants. Thousands of dollars are being saved by the Farnsworth System, not alone in Canada and United States, but in all countries of the world, wherever steam is used for heating or manufacturing process work—its value is thoroughly proven!

When the amount of expense saved by Farnsworth equipment is taken into consideration the question of installation costs is eliminated. It quickly pays for itself. It is a safe and profitable investment. Experience proves that in the majority of cases only three to six months' operation is required to return first costs.

These are facts. Plant owners have nothing to lose and everything to gain by investigating the Farnsworth System and the engineering staff of The Canadian Farnsworth Co. will be glad to advise and co-operate with them in solving steam line drainage and boiler feeding.

The Farnsworth Automatic Duplex Boiler Feeder

The "Farnsworth" should not be confused with ordinary steam traps. It is a machine built for Boiler Feeding. Note the cushioned dashpots, a feature which provides against shocks and ensures smooth operation.



The Sign of Coal Saving

No leaky steam valves with the Farnsworth in your plant; no constant waste of steam to the outside air; no springs to loose their tension; no levers to jump out of place; no weights to cause poundings, and no trunnions to bind and stick, or leak water and steam.

The Duplex feature of construction ensures a continuous flow of feed water to the boiler. Then, the machine being always equalized with the boiler provides against sudden shock or jar in the feed lines. There is no hold-up on the return lines as is the case with ordinary return traps, as the feeder is constantly receiving the water.

Our expert steam and condensation engineers are at your service. Have them investigate and make reports.

Your enquiries are solicited. Send for our Bulletins on Steam and Condensation — they are interesting and instructive.

THEORY AND PRACTICE OF ELECTRICITY

Continued from Page 271

The watt is a pretty small unit and when dealing with large apparatus another term is used—kilowatt. A kilowatt is simply 1,000 watts and the prefix kilo is the Greek word for one thousand.

One horsepower equals 746 watts or 0.746 kilowatts and it is thus an easy matter to convert horse-power into kilowatts or vice versa.

Electrical Unit of Work

In the first article of this series we dealt with the mechanical units of work energy and power and it was seen that work was measured in foot-pounds. It is possible to find the amount of work done by an engine of so many horse-power quite simply if we know how long it has been working, for every minute and for every horse-power, 33,000 ft. pounds of work have been done and it is simply a matter of multiplication. Another unit of work is quite frequently used—the horse-power hour and this is equal to 33,000x60=1,980,000 foot pounds.

The kilowatt is the electrical unit of power and as has been seen is exactly similar to the horsepower in meaning differing only in size. If we take the kilowatt as the electrical unit of power and the length of time in hours that the power has been exerted we can derive an electrical unit of work similar to the horse-power hour. In this case it is called a kilowatt hour and some-times the smaller unit the watt-hour is used.

The idea of work may also be explained from another aspect. The coulomb is the unit of electrical quantity and if the number of coulombs of energy transmitted per second is multiplied by the total time then we have the total number transmitted in any given interval. If this in turn is multiplied by the pressure or voltage we arrive at the work done.

Coulombs per sec. × number of seconds = total energy transmitted. But coulombs per sec. × amperes.

Therefore—

Amperes × time = energy transmitted.

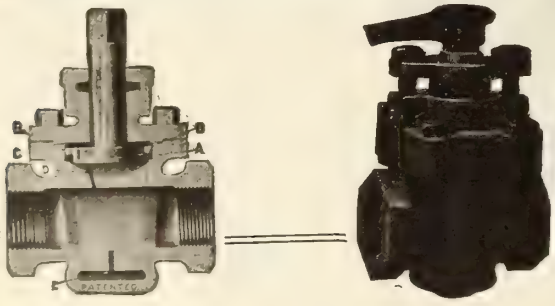
Amperes × time × volts pressure = work done.

Amperes × time in hours × volts = watt hours, or

Units of	Mechanical	Electrical
Pressure	Feet head or pounds per sq. in.	Volts.
Quantity	Pounds or cubic feet, etc.	Coulombs.
Rate of flow	Gallons per min., cubic ft. per min., etc.	Ampere.
Power rate of working	Head in feet × rate of flow in pounds per min., or foot pounds per minute The horse power = foot pounds per min. ÷ 33,000	Rate of flow × the pressure or amperes × volts = watts. Watts ÷ 1000 = kilowatts.
Work	The foot pound. Force by distance. Rate of working by time = horse power hour.	Quantity of energy by potential Rate of energy flow by potential by time = kilowatt hours.

The Norton Company, of Worcester Mass., U.S.A., have established a factory at Hamilton, Ontario, which will be known as the Norton Company of Can- Ltd. Here they will manufacture a complete line of grinding wheels, for the Canadian market. The management will be in the hands of Mr. Robert C. Douglas. The Norton Co., of Canada will be represented by the Canadian Fairbanks Morse Co., Ltd., through out Canada, and in Quebec by F. H. Andrews & Son, and in Vancouver, B.C., by Simonds Canada Saw Co., Ltd.

HOMESTEAD
Quarter-Turn Valves



For Quick Action!

A quarter turn, and the Homestead is opened to fill area; a quarter turn back and it is closed absolutely tight by a patented wedging cam that automatically forces the plug downward.

Use them for your blow-offs, throttles, tank valves and every other service where the duty is exception ally severe and frequent opening and closing is required.

As to Feed Doors

Ask any steam engineer to look at the above illustration and tell you which feed door opening will save labor, time and fuel. His answer will be the Betson monolithic one-piece.

The wide flare of the Betson door opening makes it easy to spread the coal over the fire clear back to the bridge wall without the use of the hoe.

Betson's Plastic Fire Brick is the ideal material for back or front arches, complete boiler settings or for repairing linings. It is readily put in place by any practical man. No forms or special tools required. It will outlast any other boiler furnace linings. Air tight — jointless — free from expansion and contraction and will not spall.

Send for pamphlet, showing how to use Betson's Plastic Fire Brick in your boiler room.

BETSON PLASTIC FIRE BRICK CO., INC.

NON-CORROSIVE

CYLINDER OIL

MANUFACTURED ONLY BY

E. H. KELLOGG & CO.

NOS. 242 TO 248 SOUTH ST. NEW YORK, U.S.A.

FRICTION LOSS

An overload is often a necessity. But it is hard on an engine. To successfully carry an overload so that there will be no after effects on the engine a very careful selection of your oil should be made. An oil that is not free from impurities will cause a greater wearing on the bearings, a great friction loss will occur. You will need to fire the boiler more often because the engine will be harder to run. In this manner you lose out. You work harder, have larger operating costs, and less power all because of your oil. Do as a great many Canadian engineers have done — give Kellogg's "Non-Corrosive Cylinder Oil" a trial. Absolutely pure. Write us regarding it.

E. H. KELLOGG & CO.,

New York, U.S.A.

ENGINEER WANTED

WANTED—July first, engineer for Montreal with first-class certificate, competent to take charge of large heating, electrical and refrigeration plant.

Apply stating former experience and give reference to Box 3120, Montreal.

(P.H. 6-5)

When writing Advertisers kindly mention this paper

American Manufacturer Wants Representation in Canada

Our proposition should interest an established machinery supply house now calling on steam power plants in Canada. For particulars, write Box 518, Power House.

(H) P.H.

Use The LONG STEAM *for* TRAP SATISFACTION

kettles, separators, steam mains. Works against 1 to 200 pounds pressure. Has two outlets and is installed in any position. DOESN'T FREEZE.

The Hamilton Powder Works, Beloeil, P.Q., use them with great success. **Read this letter.**

Dear Sir: We have used one of your steam traps for a long time and have found the same to answer the purpose as well as any seen in operation. We were so pleased with the working of this steam trap last winter that we ordered six more this season and have fitted them up at various points in the works where live steam is used for heating purposes.

(Signed) J. Murray Wilson,
Superintendent

Our trap will give you the same satisfaction as recorded above. Investigate and you'll be satisfied, too.

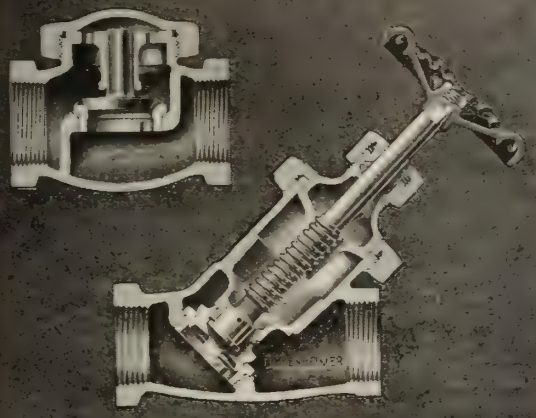
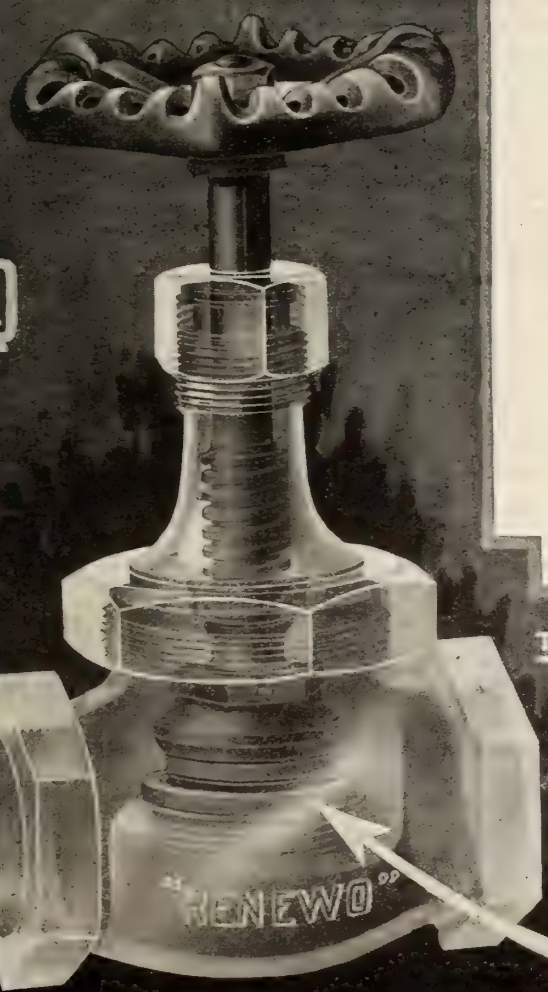
LUNKENHEIMER "RENEWO" VALVES





Have achieved an enviable record for economy in steam service. They represent the highest development in valve construction, incorporating all the good features discovered and developed in over half a century of valve manufacture.

Their installation means permanence in the line, because they are as near wear proof as can be attained, and to further enhance their durability all the parts are interchangeable and can be replaced should necessity require.

"Renewo" Valve parts are made of materials best suited to the duty the part performs.

The ***Renewable Seat*** and ***Disc*** are made of Lunkenheimer "Valve-nickel," a material having exceptional wear-resisting qualities; the Disc is provided with the celebrated Lunkenheimer "Seat-guard" which aids in preserving the seating faces and keeping them clean, and the seating surfaces are regrindable. The stem is made of a special bronze; the thread is extra long and has full contact when valve is opened or closed.

The union bonnet connection with outside protected threads; deep stuffing box with gland follower, and the self-cooling malleable iron handwheel are other points of merit.

Globe, Angle, Cross, Straightway or Y and Horizontal and Angle Check Patterns for 200 and 300 pounds working steam pressures. Specify LUNKENHEIMER "RENEWO" and insist on having the genuine.

Turbo Generator Units

25 Cycle

1—8000 K.W. (Normal rating) Allis Chalmers Turbo-Generator, 3 phase, 4 pole, 6600 volt, rotating field, condensing high pressure 175-lb. gauge at throttle, 28-in. vacuum. Will not exceed 18-lb. dry steam per K.W. when working under full load. Condenser: 16,000 sq. ft. surface Condenser with auxiliaries. Will sell with or without Condenser.

1—6000 K.W. General Electric-Curtiss Horizontal Turbo Unit, 3 phase, 6600 volts. 1500 R.P.M., non-condensing, with exciter, expansion joint, etc., 170-lb. steam pressure.

1—2500 K.W. Westinghouse-LeBlanc Turbo Unit, 3 phase. 2 pole, 2400 volts, 1500 R.P.M. Condensing, 150-lb. pressure, dry and saturated steam, 28-in. vacuum. With Condenser.

1—2500 K.W. Westinghouse-Parsons Turbo Unit, 3 phase, 2200 volt. 1500 R.P.M. 150-lb. steam pressure.

1—2500 K.W. Westinghouse-LeBlanc Turbo Unit, 3 phase, 2400 volt, condensing 150-lb. steam pressure. 28-in. vacuum.

1—2000 K.W. General Electric-Curtis Vertical Turbo Unit, 3 phase, 2200 volt, 750 R.P.M., 4 pole, 150-lb. steam pressure. 6750 sq. ft. Surface Condenser with auxiliaries.

1—850 K.W. Westinghouse-Parsons, horizontal Turbo Unit. 3 phase, 380 volt, 1500 R.P.M., 150-lb. pressure, 3000 sq. ft. Surface Condenser with auxiliaries.

1—750 K.W. Westinghouse-Parsons, mixed pressure Turbo Unit, 3 phase, 380 volt, 1500 R.P.M. Steam conditions 15.5-lb. absolute, 28-in. vacuum, with condenser.

1—750 K.W. Westinghouse Turbo Unit, 2 phase, 440 volt, 1500 R.P.M. Condensing. With Condenser and auxiliaries.

1—500 K.W. Westinghouse-Parsons Horizontal Turbo Unit, 3 phase, 2 pole, 370-400 volt, 1500 R.P.M. Condensing. 150-lb. steam pressure, no superheat. With Condenser and auxiliaries.

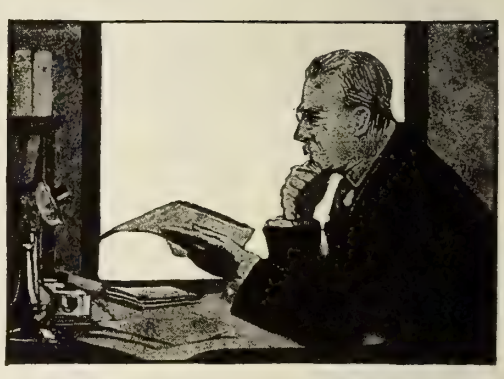
Buyers and Sellers of New and Used Machinery

A Continent-Wide Service

Tell it to the front office



Tell the boss that you are tired of fussing with troublesome traps that waste your time and his money. Send him that new book we have for you—and let him see why the Dunham Trap has been installed in so many prominent residences, public buildings, apartments and industrial plants.

Tell him that the Woolworth Building and many of the largest office buildings in Canada use Dunham Traps exclusively. Remind him that it was the first thermostatic disc trap; has been standard since 1903 ; has only two parts ; is permanently adjusted at the factory; makes jet water unnecessary.

First, send for the book, "Data on Dunham Heating." It's worth having.

"FEATHER" VALVE AIR COMPRESSOR

1000 Pounds Pressure and the "FEATHER" Valve

(REG. U. S. PAT. OFF.)

THE "FEATHER" Valve in Worthington Air Compressors, which successfully stands pressure up to 1000 pounds, is a thin strip of ribbon steel.

The "FEATHER" Valve is the strongest, most simple, long-lasting valve in service. It has but one moving part—"a ribbon of steel," which weighs less than one ounce, and functions by bowing in center against slotted curved guards to permit passage of air or gas and closes by gently straightening into place on ground face slotted seats. There is no friction or hammering action as with many other types of valve.

The "FEATHER" Valve, because of its efficiency, prevents fluctuating pressures and guarantees an always ready, reliable air service for Shop, Foundry or Mine.

Here again is proved the worth of Worthington's 80 years' experience in designing and improving pumps and pumping machinery. The advice of our engineering experts is to be had for the asking.

Clearance Sale of High Grade Technical Books

FOR several years we have maintained a Technical Book Department, handling high-class books published by various well known publishers. For various reasons we have now decided to discontinue our Book Dept. and in order to clear out what stock we have on hand we offer the following books at prices considerably lower than the regular selling price. Each item represents high quality at bargain prices. These books will not last long—first come first served. This is a fine opportunity to add to your technical library.

Title of Book.	Name of Author.	Binding	Number of pages	Illustrated	Price
Electric Chemistry	G. W. Cravens	Cloth	132	Yes	$1.10

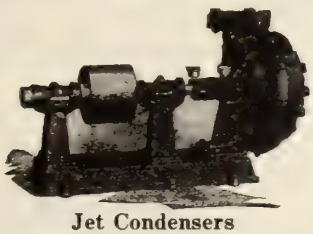
LEONARD

AMERICAN-MARSH PUMPS

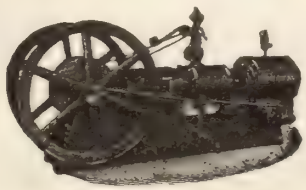
SIMPLE RELIABLE EFFICIENT

The American-Marsh steam pump is an improved form of the famous Marsh Pump which has been on the market for over thirty years, during which time over 150,000 have been manufactured and sold.

The American-Marsh Pump has no internal stuffing boxes, no tappets and no slide valves. The auxiliary valve is of the semi-rotative disc type of an improved design. The main steam valve is of the balanced piston pattern, assuring highest efficiency. The water ends have large valve areas and are fully bronze fitted, including solid bronze piston rods and bronze removable water cylinder bushings.



American-Marsh Centrifugal Pumps are made with the same high grade of material and workmanship which characterizes the construction of the steam pumps. They are made in all sizes up to 12 inch, both single and two stage for heads up to 250 feet.



The line also includes—

Power Pumps
Deep Well Engines
Air Compressors
Jet Condensers
Dry Vacuum Pumps
Boiler Feed Pumps

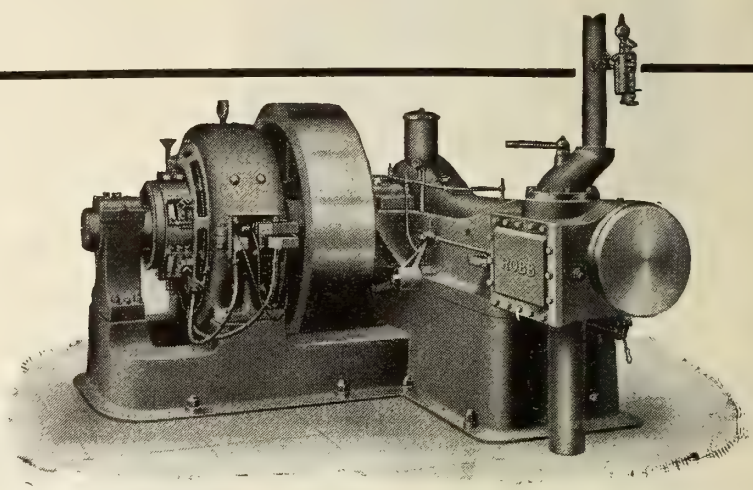
ROBB POWER PLANTS

For Quality Equipment

We specialize in the design and construction of power plant equipment. Our engineers are prepared to investigate your problems and advise on the most economical machinery for your needs.

We can supply Corliss, Slide-Valve, Vertical, Horizontal, Simple and Compound Engines, and Water tube, Return tubular, Improved Scotch Marine, and Portable Boilers.



Robb Equipment is known to engineers and power plant superintendents for its long and dependable service, standard quality and modern design. When you are in the market—remember it will pay you to purchase equipment that has won the confidence of leading engineers.

KNOW

How much steam you use for each different purpose

St. John Indicating and Recording Steam Meter

TO know costs, you must be able to determine the exact quantity of steam used in the operation of your engines, pumps, blowers, laundries, steam kettles, heating systems, drying rooms, or for other purposes. The St. John Meter measures the flow of steam at all pressures and under varying loads.

It gives you a graphical minute-by-minute record, on a paper ribbon, of the exact number of pounds of steam used during any period of time. Guaranteed accurate to within 2 per cent.

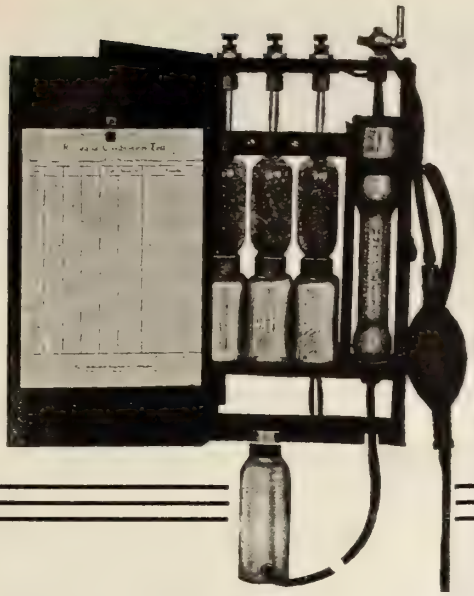
When You Buy Hays Equipment You Buy Hays Equipment



The Hays Improved Gas Analizer

From Guess Work to Exact Knowledge

FUEL is scarce and high in price; you can't afford to waste it. Excess or insufficient air, leaky boiler setting, leaky baffles, holes in the fire, fires too thin or too strong—these are some of the conditions which waste your fuel. You can't locate them by guesswork.

Hays' Combustion Efficiency Appliances indicate **exactly** how the waste is occurring. Your engineer is then in a position to stop it.

Small plants as well as large ones greatly benefit from Hays Equipment. Just what it can accomplish in **your** plant, our service department will tell you. Put it up to them—their service costs you nothing.

Let us send you a copy of our book, "How to Build Up Furnace Efficiency." You will find it of absorbing interest.

Hays Automatic CO_2 and Draft Recorder awarded Certificate of Merit by the Franklin Institute.

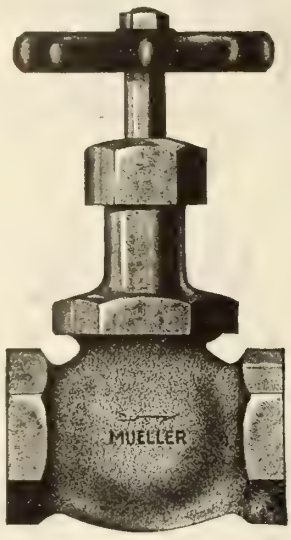
MUELLER
BRASS GLOBE VALVES



Registration Numbers:

Province of Ontario No. 1780
for 175 lbs. pressure.

Province of Alberta No. 1116
for 150 lbs. pressure.

MUELLER Brass Globe Valves are recommended for a working pressure of 125 lbs. The special features appended justified voluntary registration for working pressures of 175 lbs. and 150 lbs. by the Chief Boiler Inspectors of Ontario and Alberta respectively:

DESIGN
Special barrel shaped body. Female thread on bonnet.

METAL
High copper and tin content giving a tough, close grained casting with pressure resisting qualities.

PACKING
Special packing composed of asbestos and graphite with lead core wire to resist high pressure.

MUELLER Globe Valves are being substituted for competitive patterns of composition disc Valves.

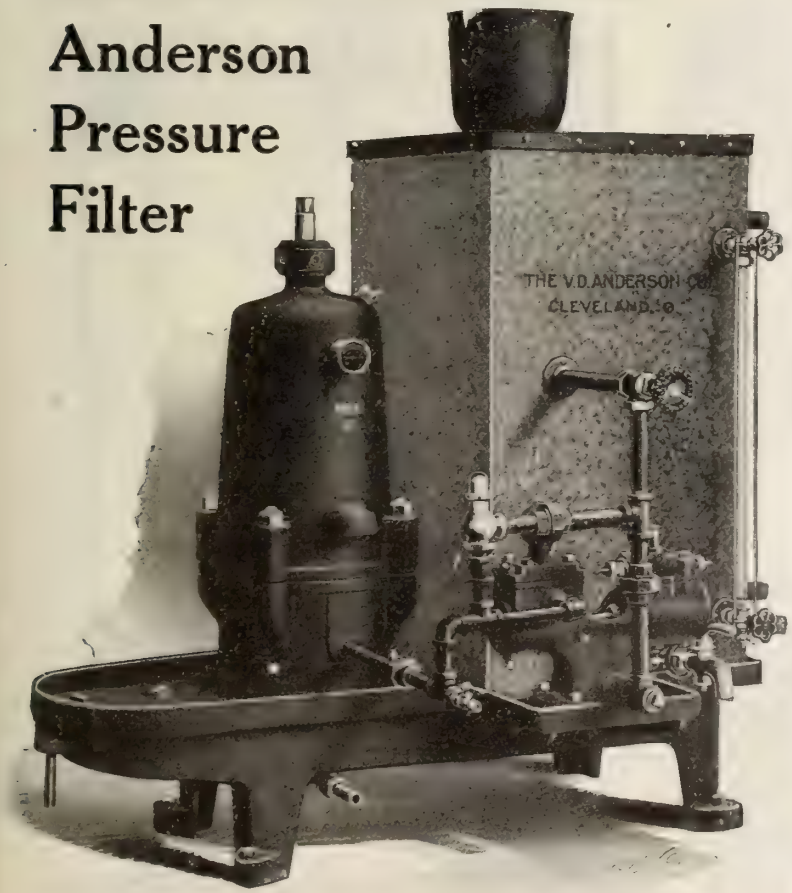
Anderson Pressure Filter



Get Twice the Use from Your Oil

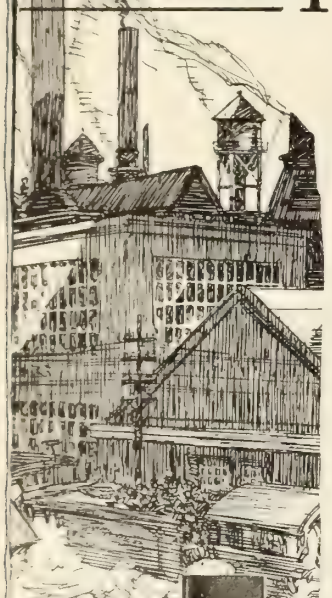
Put your drip-pan collected oil through the Anderson Pressure Filter. It goes through a cleansing and purifying process identical to that of the refiners. It comes out suitable for use on the finest bearings.

Without the Anderson your expense for oil is double what it should be. To get the benefit of that other 50% the first step is to send for our catalog. It explains in detail just how the Anderson Pressure Filter prevents waste.

The V. D. Anderson Co.
West 96th St., Cleveland, Ohio

Where every Working minute means money, blown fuses cut profits unless electrical circuits are protected by

ECONOMY *renewable* FUSES



INDUSTRIES using electrical energy operate most efficiently when delays in machine operation are unnecessary while blown fuses are being replaced.

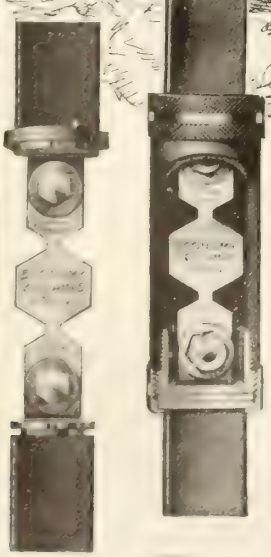
Economy Fuses are used by thousands of industries because they permit of renewal in minimum time at minimum cost.

Where greater efficiency is required a reserve stock of fuses is kept on hand and used in case of blowouts. The blown fuse is then restored to duty at leisure by simply inserting a new Economy "Drop Out" Renewal Link.

Economy Fuses cut annual fuse maintenance costs 80% as compared to the use of "one-time" fuses.

The fibre cartridge, the winged washers which lock the fuse, and the threaded end caps which complete the assembly are virtually indestructible and are used over and over again.

Economy was the first line using inexpensive bare renewal links for restoring blown fuses to their original efficiency to be *Approved In All Capacities* by the Underwriters' Laboratories.



For sale by all leading electrical jobbers and dealers

Simple and Practical Vacuum Pump

The fact that Nash Hytor Vacuum Pumps are in extensive use in many of the largest engineering plants is sufficient evidence of their superior qualities.

These pumps are manufactured on the limit system, with Johansen measuring blocks as a reference. Interchangeability of all parts is assured. Each pump is tested for capacity, vacuum and horse power before it leaves the factory.

Nash Hytor Vacuum pumps have only one moving part, the rotor, supported on a very heavy, carefully proportioned shaft. All valves, sliding vanes, pistons, gears, crank shafts, cams or rubbing surfaces are eliminated.

If you are interested in learning more about the many valuable features of these pumps. Write us. All enquiries will have immediate attention.

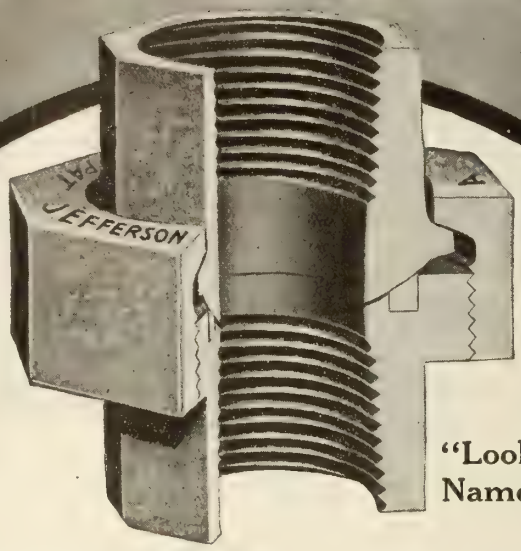
JEFFERSON



"Look for the Name on the Nut"

EVERY practical engineer will recognize the value of a **brass-to-iron** joint in pipe Unions. Jefferson Unions have a brass seat ring embedded into the malleable iron by exerting enormous pressure—up to 40 tons. This does away with the possibility of corrosion and the seat ring cannot become dislodged under any conditions. This seat ring is ground accurately to fit the spherical face of the other part of the union, thus insuring a tight joint even though the pipe is slightly out of line. The uniform perfection of JEFFERSON UNIONS insures against breakdowns and dangerous steam losses. Your Jobber has them in stock. You've nothing to loose by giving them a trial.

We would like to tell you of the many other Jefferson strong points—these are covered in detail in our new catalog. Send for your copy to-day.

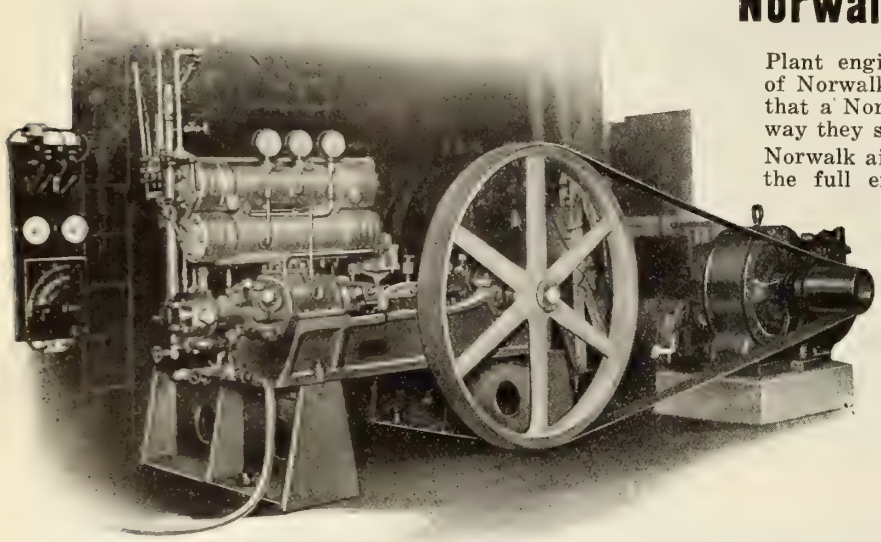
NORWALK
AIR & GAS · COMPRESSORS



A Norwalk Compressor on Testing Stand.

Norwalks Always Do Their Work

Plant engineers are liberal in their commendation of Norwalk compressors, because "you always know that a Norwalk is going to do its work," That's the way they sum up the situation.

Norwalk air and gas compressors have been meeting the full expectations of critical engineers for so many years that their reliability is unquestioned. Every Norwalk is thoroughly tested for more than specification pressure before leaving the plant. It never goes out until it has passed the efficiency test.

Norwalk bulletins describe and illustrate Norwalk compressors for air, oxygen, hydrogen, carbonic acid, gas and acetylene. Sent on request.

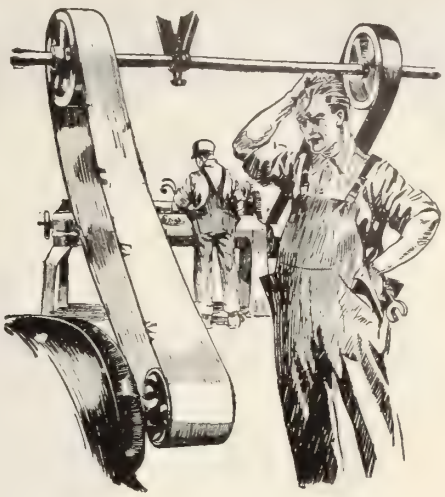
KERR
("New KEYSTONE" Pattern) GATE VALVES

If you have not used any of these New Pattern Valves, specify "KERR" in your next order. We want you to get acquainted with the most reliable valve on the market.

If you have been using them, we are confident that our satisfaction will bring us your repeat orders. These valves will never cause you or your customer the slightest trouble. Their high quality is consistent.

When you buy a "KERR" Valve you get a guaranteed article that is backed by a reliable firm. Many of the largest distributers of valves in Canada have sold "KERR" Valves for over 25 years, and are still recommending them as the "Best Valve." Write us for particulars.

Kerr Engine Co., Ltd., Valve Specialists **Walkerville, Ont.**



Curing a Mean Drive

Practically every factory of any size has one or more mean drives which seem to defy all attempts to correct them.

Up to date you're beaten—but that's because you want to solve the problem yourself.

Our transmission experts take more real satisfaction in solving mean drives than in selling belts.

Dominion Friction Surface Belting

has helped to solve many transmission problems, and we have yet to find a drive where it will not provide efficient, satisfactory service.

It will cost you nothing to have one of our belting experts study your problem.

If he can't help you he will tell you so. If he can help you it will cost you only the price of a belt that will give you a longer and more satisfactory service than any other belt has given on that particular drive.

The first step to that satisfactory service is a 'phone or wire to our nearest service branch.

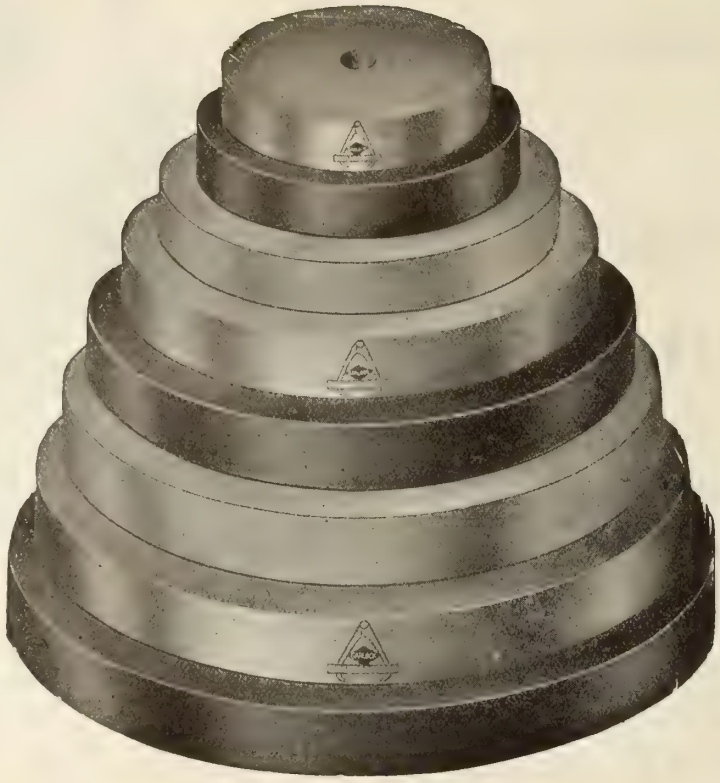
GARLOCK

PUMP



VALVES

The service of pump valves depends upon the compounds as well as the consistency and cure of the valves. The compounds used in Garlock pump valves have been established after years of trial in actual service and under the most severe conditions. Pump valves should always be used for the purposes for which they are intended. The following are a few of our leading styles and grades of valves:

Style No. 139—For medium pressure cold water
" " 175—For high pressure cold water
" " 182—For warm or greasy water
" " 108—For hot water
" " 105—For boiling water
" " 154—For air compressors and condensers

We guarantee our pump valves to give satisfactory service when used under conditions for which they are intended.

LINCOLN ARC WELDING

Get That Boiler Repaired With Lincoln Electric Welding

because it will make a permanent repair for you in as many hours as it takes days by any other method.

Therefore, by shortening the time of the "tie-ups" due to leaky defective boilers, this process is an economical one that every plant superintendent and owner should be informed about. It will not obligate you in any way if you will write for particulars about Lincoln Electric Welding.

Possibly it would not pay you to install a Welder of your own. In that case it might be advisable for you to utilize our welding plant located after June 15th, in new and enlarged quarters at 136 John St., (at present at No. 1 Jarvis St.) where we have, in addition to our regular outfits, portable equipment ready for emergency calls.

"Link Up With Lincoln"

How Well Do YOU Know Canada?

Gripping
Amusing
Informative

MACLEAN'S
"CANADA'S NATIONAL MAGAZINE"

One of the best edited publications in the world.

Contents of the Big June 1st Issue

"Parliamentary Dog Days." J. K. Munro. Illustrated by Lou Skuce. Canada's wittiest and shrewdest political writer gives us his regular monthly summary of the situation at Ottawa—replete with "inside information."

"Bertie and the Bolshevik." By A. Raymond Mullins. Illustrated by C. W. Jeffreys. A most humorous tale of an English soldier in Canada who gets "taken in" by a bunch of Bolsheviks.

"The Parts Men Play." By Arthur Beverley Baxter. Illustrated by H. Weston Taylor. Another gripping instalment of this great Anglo-American-Canadian serial.

"They're All Alike." By Mary E. Lowry. Illustrated by D. G. Summers. A delightful love story, with the scene laid in a big Canadian city.

"The British in Italy." By Brigadier-General Mitchell, formerly Chief of the Intelligence Staff of the Canadian Army. Illustrated by photographs. The first authorative recital of the part the Canadian troops played in the Italian campaigns.

"The March of the Overall." The Canadian Press, from Coast to Coast, treats in a fecitious manner with the craze for Blue Jeans.

"The Little Warrior." By Pelham Grenville Wodehouse. Illustrated by C. W. Jeffreys. A long, absorbing instalment of this masterpiece of humor—the finest serial story MACLEAN'S has ever run.

"A Safe Bet." By W. A. Fraser. Illustrated by R. M. Brinkerhoff. It's about a horse race in Montreal, and it's one of the best stories this world-famous sporting writer has ever written.

"Is Era of Wildest Prosperity Ahead of Canada Today?" Canada is in the strongest economic condition of any country in the world, says Agnes C. Laut, famous international authority, in a strikingly prophetic article which you'll keep for future reference.

Review of Reviews

"Will Colored Hordes Submerge the World?" By Lothrop Stoddard.

"Why Gasoline is High." By John K. Barnes.

"Eccentricities of a Despot." By A. C. Jewett.

"Holland is Too Wealthy." By Oscar T. Schweriner.

"To Probe Secrets of the Air." By Lloyd V. Turner.

"Russia is Turning to Germany." By Baron Eugene De Schelking.

"Odd Marriage Custom in Ireland." By Albert E. Knash.

"Embassy Mistakes." By A. Maurice Low.

"Two Million Extra Women." By William Ord Barker.

"P. M. S." BELTS

The unusual flexibility of P.M.S. Belts gives perfect conformity to pulleys, large or small, and is especially adapted to toper cone drives in Paper Mills —the most difficult belt test known. This unusual adaptability increases pulley contact and prevents loss of power. Where extra heavy loads are carried, P.M.S. Belts are particularly appreciated.

Conveyor Belts and Transmission Belts for All Sorts of Machinery and Conditions of Service

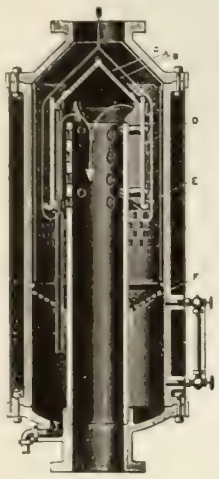
III IMPORTANT THINGS
TO CONSIDER ABOUT
A SEPARATOR



I. THE PLAN—Is it sensible, will it work, no matter how large the Separator or how well made?

II. THE SIZE — Is it big enough regardless of plan, will it hold a good dose of water?

III. THE CONSTRUCTION — Is it strong enough, are flanges heavy, how will it look by the side of a nicely finished engine? Send for catalog and note these points in

Sweet's Separators

Voorhees Rub-Steel Valves

THE SUPERHOT GRADE

for high temperature work such as: Boiler Feeds, Locomotive Boiler Washing, Condensing Against High Heat and Oily Matter, Oil Refinery Service, Vacuum Returns on Heating System. For mild acids, etc. This Valve will not buckle under quick interchange of the temperatures.

One installation will convince YOU.

Booklet on Request

The Canadian Fairbanks-Morse Co., Limited
Sole Distributors for Canada

DURABLA
TRADE MARK REGISTERED

STRENGTH—GOODNESS—QUALITY

Performance Facts of Durabla Gasket Material

Tight joints are made and maintained by DURABLA under the following severe services and conditions:

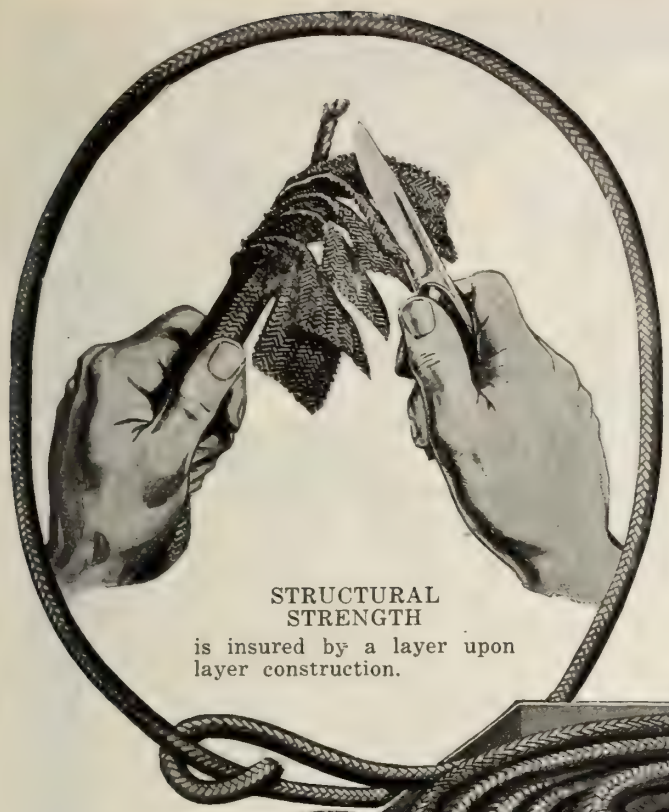
Steam:	275-300 lbs. pressure; 275°-300° superheat.
Oil:	Pressure still joint re-made over 160 times.
Gasoline:	Cylinder heads of gasoline engines and pumps.
Acids:	All acids that can be carried in pipe lines.
Water:	Equally satisfactory with temperature of 40° or 210° F., at any pressure.
Ammonia:	Both absorption and compression systems of refrigeration.
Air:	Air lines and cylinder heads of compressors—all types.

One Standard material for all gasket work—Sold on a Service Basis

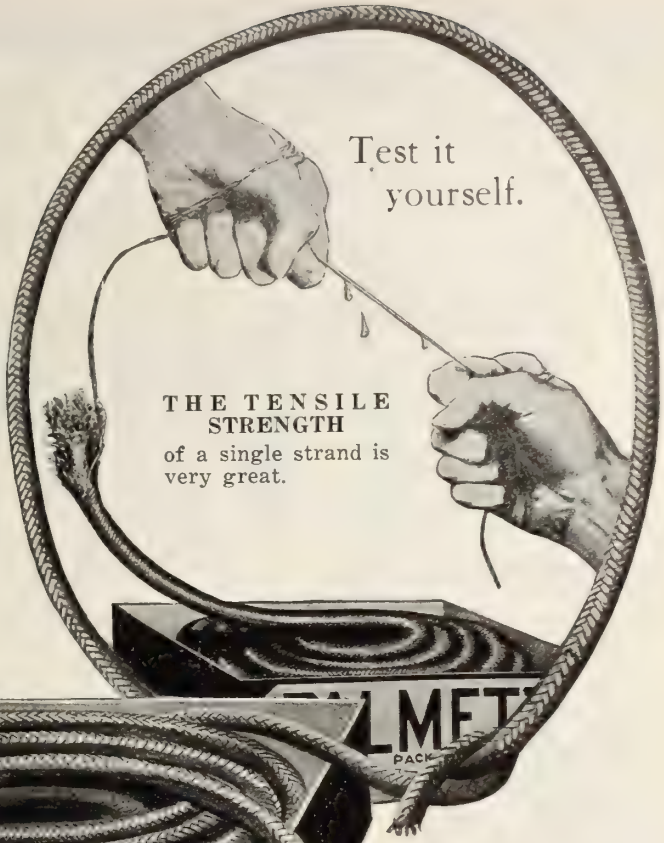
DURABLA is sold in sheet or gasket form and the trade mark is stamped all over the material.

DURABLA MANUFACTURING CO., NEW YORK
Distributors for Canada: The Canadian Fairbanks-Morse Company, Limited

DURABLA



STRUCTURAL STRENGTH
is insured by a layer upon layer construction.



Test it yourself.

THE TENSILE STRENGTH
of a single strand is very great.

Three Reasons why "PALMETTO" PACKING

is superior for high pressure, superheated steam and compressed air.

It gives longer service than other packings and is therefore more economical.

Let us send you a working sample to test under your own conditions—no charge.

GREENE, TWEED & CO.
Sole Manufacturers
109 Duane St., New York

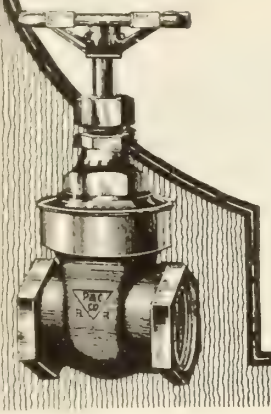
Canadian Agents:
The Canadian Fairbanks-Morse Co., Limited, Montreal, Ottawa, St. John, Toronto, Winnipeg, Calgary, Saskatoon, Victoria, Vancouver.

Its graphite grease lubricant prevents friction.

Lubricant is forced into each single strand before braiding.

"Stop Thief!"
Save Your Valves!

When you throw away a valve because the seat is worn out, it's as if someone had stolen that valve from you.
Why don't you stop that extravagant waste? Why don't you scrap only the worn seat instead of the whole valve?
With a PRATT & CADY RENEWABLE GATE VALVE the seat rings save the valve—they save you almost the entire cost. You can insert a new set of seat rings for around 10% of the cost of a new valve. Then the valve is as good as new.
And you can put in the new rings without removing the valve from the line.



PRATT & CADY
Renewable Seat Gate Valves

are saving money for hundreds of other firms—why not for you?
Pratt & Cady Valves have long life. They are designed to stand up under hard work.
Are double seated, so that the pressure can be applied at either end.
Bronze or iron in all standard sizes—for Steam, Air, Oil, Gas or Water.
Cutout valve reseating machines. Forget the trouble of scored seats.
Send for instructive valve book.

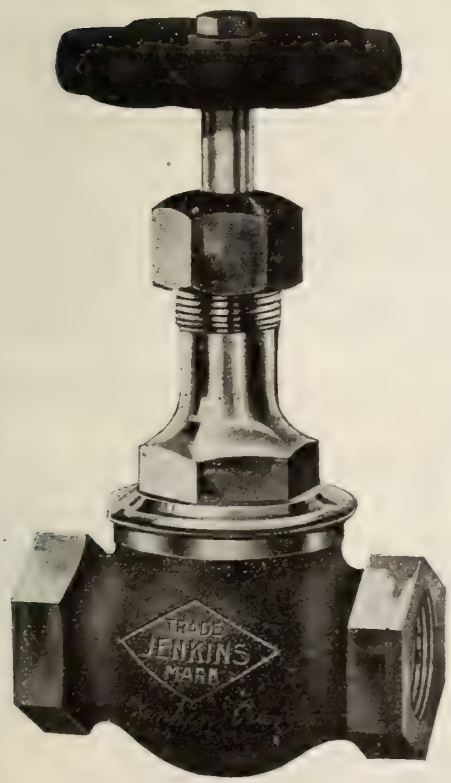
TRADE JENKINS MARK

Jenkins Bros.

There's a Jenkins Valve for every purpose

The Diamond Trade Mark is cast on every genuine Jenkins Valve



Low Maintenance Costs

Economy is not a matter of buying that article which is lowest in price, but of buying that which will give the greatest **service** for your money.

Over half a century of experience goes into the manufacture of Jenkins Valves. Jenkins Valves give no trouble once they are installed. Their long reliable service reduces upkeep expense to a minimum.

Standardization makes every Jenkins Valve of equal quality. The performance of one is equalled by every other.

Be sure of your new equipment. See that the valves you receive have the Diamond Trade Mark cast on the bodies.

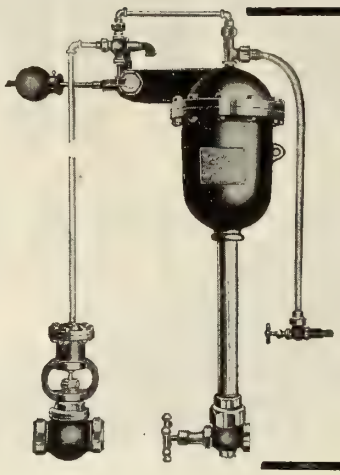
Why not Buy the Best, when in market for Packing?

HOLMES' Metallic Packing Is Guaranteed 3 Years

Lasts many times longer. 30 days' trial. Less oil. No cutting. Easily applied to any Steam Engine, Air Compressor or Gas Engine. Satisfaction or no pay. Write us.

HOLMES METALLIC PACKING CO., Wilkes-Barre, Pa.

Incorporated 1897



Make Sure of Constant Level and Stop Worrying

Eliminate the danger of boiler explosion due to low water or a wrecked turbine or engine due to high water by feeding your boilers automatically with

Vigilant Water-Feed Regulators

They hold the water level constant at middle gauge — the safest and most logical point — that insures better economy and protects the boiler against excessive expansion and contraction.

A paying investment for any plant. Write for Catalogue now

LAURIE & LAMB
Board of Trade Building, Montreal

DEPARTMENT OF LABOUR
Ontario Government

Minister: Hon W. R. Rollo **Deputy Minister: W. A. Riddell, Ph.D.**

NOTICE TO STATIONARY AND HOISTING ENGINEERS AND STEAM PLANT OWNERS

Everyone operating a **Stationary** steam plant of 50 B.H.P. or over, and everyone operating a **Hoisting** steam plant working at a pressure of 20 pounds or over, irrespective of horsepower and used for hoisting in structural operations or excavating purposes, in the Province of Ontario, must hold a certificate from the Board of Stationary and Hoisting Engineers. Application forms will be forwarded upon request.

After January 1, 1920, all stationary steam plants in the Province of Ontario must be registered with the Board of Stationary and Hoisting Engineers. Application forms will be forwarded upon request.

All applications should be mailed to the Chairman of the Board. W. C. McGhie, Department of Labour, 15 Queen's Park, Toronto.

NOTICE TO MANUFACTURERS, DEALERS AND USERS OF STEAM BOILERS

All steam boilers built in, or entering, the Province of Ontario, and boilers exchanged or repaired, are subject to Government Inspection as prescribed in the Steam Boilers' Act, 3 George V., ch. 61.

Before any work of repair or alteration is commenced on any boiler, notice must be sent to the Department stating the nature and extent of the repairs or alterations proposed to be made. If the Chief Inspector should consider such repairs or alterations of an extensive character, the boiler must be inspected in accordance with the Regulations by an Inspector authorized under the Act.

All communications should be addressed to the Steam Boiler Branch, Department of Labour, 15 Queen's Park, Toronto. D. M. Medcalf, Chief Inspector of Steam Boilers.

MONCRIEFF'S

"UNIFIC" GAUGE GLASSES

The British Navy uses "Moncrieff's" "Unific". It is the kind that lasts. It is a special feature of the "Unific" that it does not readily corrode; resists extreme changes of temperature and withstands the highest working steam pressure. In consequence it has a long life, justifies a higher price than the soda lime glasses, and is, indeed, the more economical purchase in the end.

Write for our catalogue.

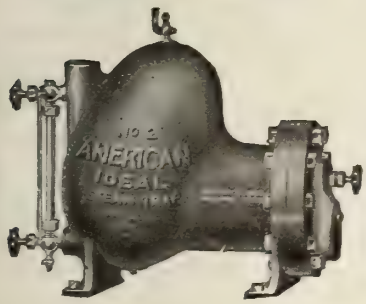
Complete Steam Trap Service



means:

Removal of all excess condensation without loss of steam, No maintenance expense.

This service is given by the AMERICAN IDEAL STEAM TRAP.

Saving Steam is saving Coal.

Saving Coal is saving Money.

Saving Coal is more vitally necessary now than ever before.

Write for our Trap Booklet.

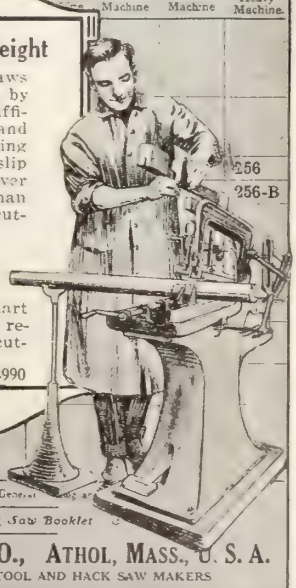
Over 18 gage	102	252			

Put On the Weight

More hack saws are ruined by using insufficient weight and pressure, letting the saw slip and slide over the work, than by actual cutting.

Get a copy of the Starrett Hack Saw Chart "CD" and reduce your cutting costs.

42-990



Numbers above are those given in the Starrett General Catalog and Machinists' Handbook

Your Oil-Fired Boilers must Be Cleaned---All Soot Deposits Removed ---Several Times Daily.

You want your boilers to operate efficiently—but if you want to keep up steam when the soot piles up you will have to shoot in more oil.

Soot deposits from oil-fired furnaces have a much greater insulating effect than those occurring with coal-fired furnaces, because the deposits being of a somewhat fluffy, adhesive nature, usually envelop the entire tube.

Hundreds of oil-fired boilers are now equipped with Diamond Soot Blowers.

Write for full information on Diamond Installations on oil-fired boilers, requesting your copy of Bulletin 280.

DIAMOND SPECIALTY CO.
Windsor, Ont., Canada

When Buying Thermometers

There's Just Three Things to Remember—

First, you must have accuracy and sensitiveness—

Second, durability is absolutely essential—

Third, the thermometer must be suitably constructed for the intended application.

Accuracy, sensitiveness and durability are absolutely guaranteed in

"Crescent" Thermometers

And with nearly seventy years of experience to our credit, we are qualified to properly interpret your needs.

Our Catalog P.H. 200 illustrates and describes "Crescent" Thermometers for every application Also test thermometers, glass thermometers, etc.

Get a copy of Catalog P.H. 200 to-day.

The Schaeffer & Budenberg Mfg. Co.

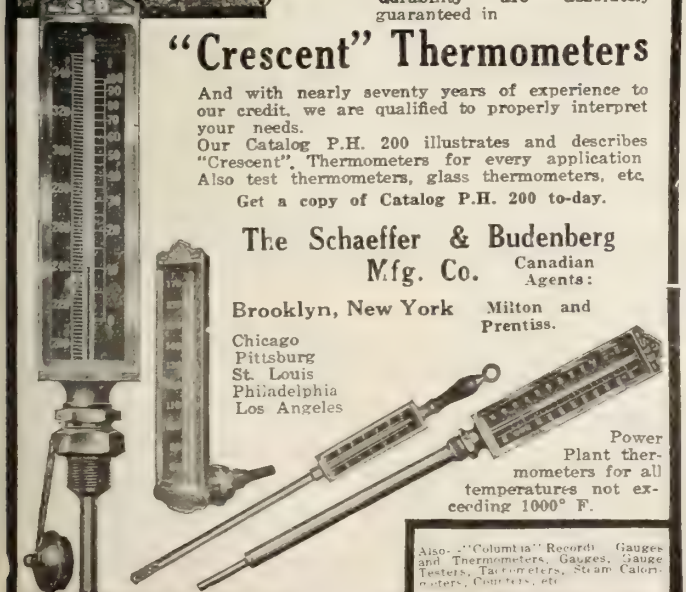
Canadian Agents:
Milton and Prentiss.



Power Plant thermometers for all temperatures not exceeding 1000° F.

Also—"Columbia" Recording Gauges and Thermometers, Gauges, Gauge Testers, Tachometers, Steam Calorimeters, Counters, etc.

In Bulk

SAFETY PLASTIC

METALLIC PACKING

For steam, water, air, gas, etc. Self-lubricating. Practically frictionless.

Pat. December 22, 1903.

Highest Award World's Fair, St. Louis, 1904.

GUARANTEED TO LAST THREE YEARS

Without Renewal.

Drop us a line and let us tell you all about this remarkable packing.

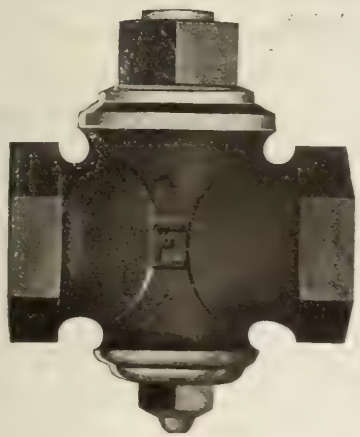
"Empire" Guaranteed Stop Cocks Stand the Pressure

It is essential that stop cocks withstand the pressure exerted upon them in the system in which they are installed. Failure to appreciate the importance of these vital links in steam systems has resulted in both loss of time and property.



A-810

Obviate this by recommending and using time-tried and satisfactory, **Empire Steam Stop Cocks.** They are rigidly factory tested and fully guaranteed. Their use is your protection and assurance of permanency.

"If its an **Empire** product you know its right."

When buying specify our lines. They are carried in stock by the larger and more progressive jobbers in Canada.

P&H FLANGED PIPE JOINTS

SCREWED

P.H. LAP

SCREWED FLANGES.—For general service, our screwed-on flange gives universal satisfaction and is the least expensive. For steam and water lines, at pressures up to 125 lbs. the flange is screwed home and not refaced. For higher pressure, we recommend screwing on the flange until the end of the pipe projects beyond the face, then refacing by taking a cut across the flange and end of pipe, insuring a perfect joint with the gasket bearing on the end of the pipe. This prevents the pressure from working through the thread of the flange, and insures a long life for the joint.

For all High Pressure service, and where it is objectionable to reduce the thickness of the wall of the pipe by threading, we recommend P&H Lap Joint.

POWER HOUSE

A semi-monthly newspaper devoted to the Generation, Transmission, and Application of Steam, Gas, Electric, Air and Water Power; and to the operation of Refrigerating Machinery.

Published by The MacLean Publishing Company, Limited, 143-153 University Ave., Toronto

MONTREAL: Southam Bldg. LONDON, ENG.: 88 Fleet St., E.C. WINNIPEG: 1103 Union Trust Bldg.

Vol. XIII.—No. 12. Publication Office, Toronto—June 21, 1920 Published Semi-Monthly Canada, $2; U.S. $2.50 a year

56 Years Service Record

The Diamond Trade Mark—

A GUARANTEE OF PROTECTION

As a tangible proof of Jenkins Valve superiority there goes with each Diamond Trade Marked Valve the following definite guarantee of service:

> "If you will put a Jenkins Valve on the worst place you can find, where you cannot keep other valves tight, and if it is not perfectly tight or does not hold steam, oils, water, acids, or other liquids longer than any other valve **you may return it and your money will be refunded.**"

Time and labor can be saved and shut-down charges for repairs and replacements eliminated by installing Jenkins Valves at the beginning. Look for the Diamond Trade Mark. It is an assurance of the best—of dependable and economical valve service under every condition of usage.

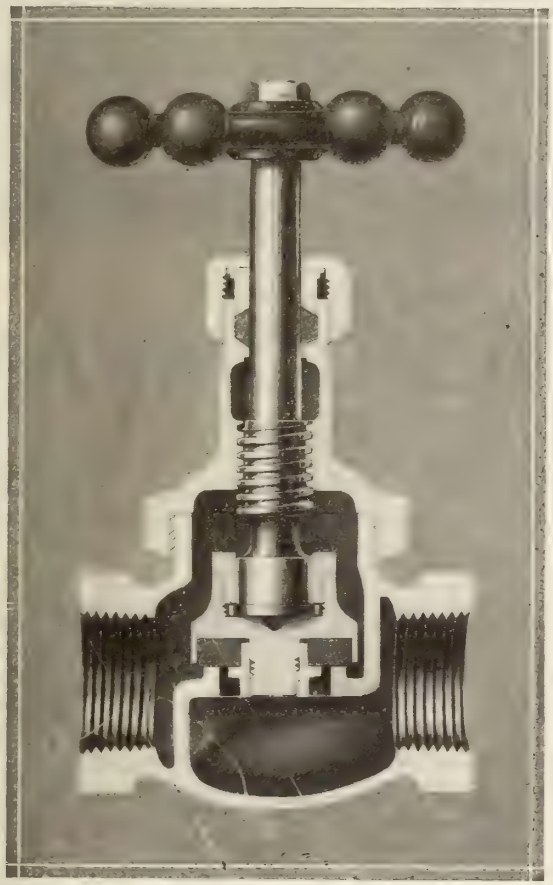
TRADE PENBERTHY MARK.

BE SURE THIS NAME is on the Valve you buy



SECTIONAL VIEW OF PENBERTHY COMPODISK VALVE
Registered and Approved for 175-lbs. Steam Pressure

Then you get "The valve with the outside bonnet construction."

The first progressive improvement made in brass valve construction in generations.

Think of the advantages ! Valve always accessible.

No straining or stripping of threads when assembling or taking apart.

Impossible to spread or enlarge body of valve when screwing down bonnet to place.

No corrosion of threads, for they are on the outside, away from the action of steam and water.

Are You Responsible

For the Efficiency of Your Power Plant ?

THEN SPECIFY "PENBERTHY VALVES

HOYT-- *for Efficient Babbitt Metals*

FOR 45 years we have devoted our endeavors exclusively to the perfection of white metal alloys. Experts have considered and tested carefully the chemical, physical and mechanical properties of each element entering into our mixtures.

Every effort has been made to place Hoyt's Babbitt Metals first on the market—every effort is made to keep them so.

HOYT'S FROST KING

For a first-class, all-round babbitt, which has been in use in many of the largest machinery plants in Canada for years—use Hoyt's Frost King.

HOYT'S DYNAMO GENUINE

As the name implies, this metal is compounded especially for dynamo and motor work. It is the only alloy that will give the best service on street car motors or any motor that runs under severe duty. It is an extremely high Copper alloy, and is as near an actual Bronze as a Babbitt can be made with success.

Largest makers of white metals in the world.

HOYT METAL COMPANY

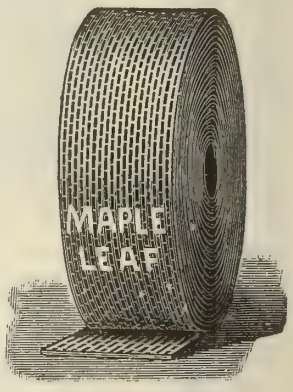
MONTREAL TORONTO WINNIPEG

Dominion Belting Company, Limited Hamilton, Canada

Sole Manufacturers of the celebrated "MAPLE LEAF" Brand Stitched Cotton Duck Belting and Belt Dressing.

The demand for our products has steadily increased because the standard of quality has been maintained.

We make only one grade, the best that can be produced.



"MAPLE LEAF" is the strongest, truest running, most economical and efficient belt on the market for transmission of power, conveying, etc.

Being thoroughly waterproof it is suitable for running in wet or dry places. **"MAPLE LEAF"** Belt Dressing is different to others offered in that it is equally good for all kinds of belting, leather, rubber or Balata, as well as our own make.

Write us for prices, and if desired we will be pleased to furnish samples and further information.

A trial order will convince you of their utility.

DOMINION BELTING CO. Ltd., Hamilton, Canada-Quebec Branch: 51 Duluth Bldg., Montreal

Capacity Production

EVERY manufacturer wants capacity production; he wants every ounce of power and work from his machinery. Volume of production is largely a matter of steady, uninterrupted work, which means that the machinery must be maintained at maximum efficiency.

To give this continuous, efficient service, machinery must be properly lubricated. Correct lubrication is inseparable from the economical operation of machines and power equipment; it is a big factor in profitable manufacturing and *you cannot afford to use any but the best lubricants in expensive machinery.*

Imperial Lubricants are well known for their high, uniform quality. They are graded for every type of machine and every moving part. They have been tested and proved under actual service conditions to be of superior fitness for the work for which each is designed.

If you have lubrication problems or difficulties, write to our Imperial Lubrication Engineers. They will gladly study your problems and submit recommendations free of charge or obligation.

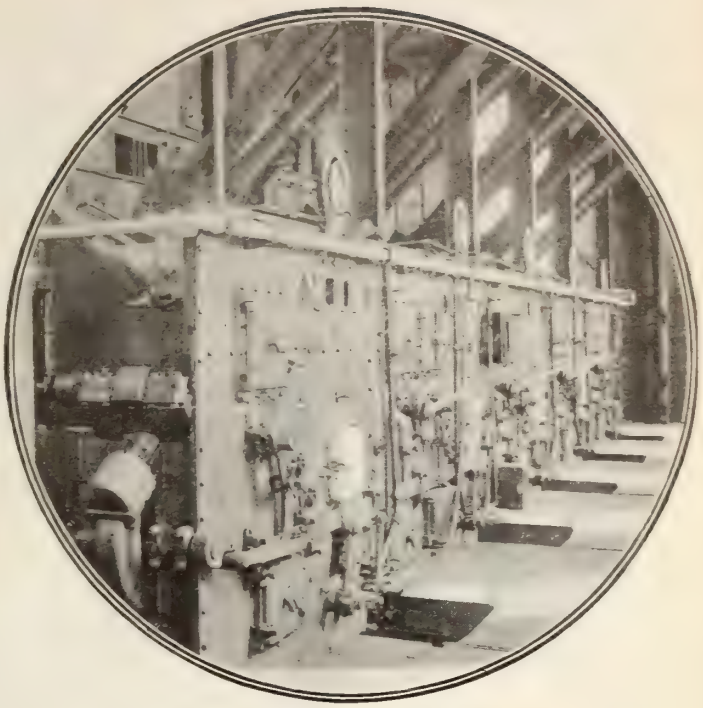
Conserve Fuel and Labor

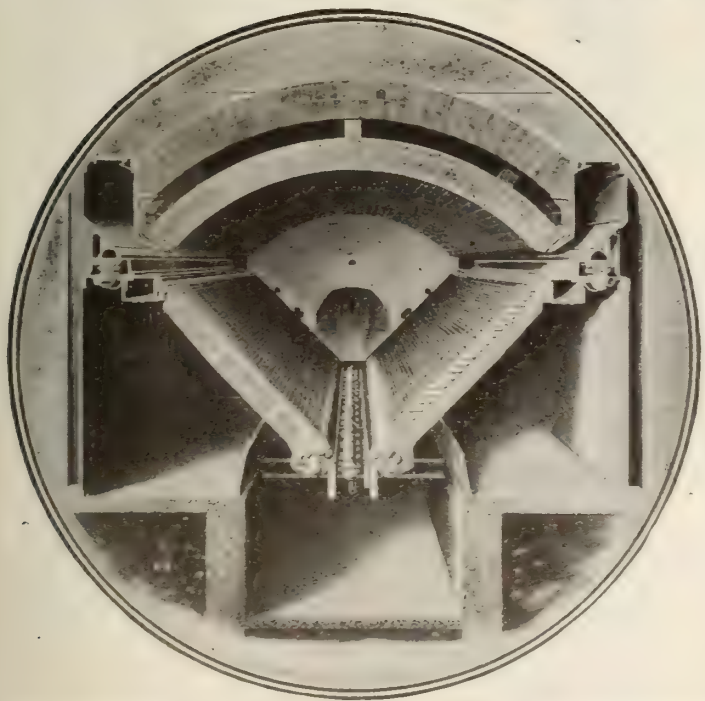


Five Murphy Furnaces as installed to fire 300 h.p. boilers

The Kalamazoo Vegetable Parchment Co. in 1916 decided to bring their power equipment up to par with the rest of their "modern mill" and installed ***Murphy Furnaces***. That they made no mistake is well recognized by the management, for in this time of great activity in the paper business, power is being furnished at the minimum of labor, fuel and expense.

Growing power demands have been promptly met because Murphy Automatic Furnaces double the normal boiler output "without one penny for draft."

MURPHY AUTOMATIC FURNACES



are highly automatic in their operation and require very little attention. The coal is fed—the fuel distributed—the fire cleaned—the ashes continuously and automatically removed.

Offset your mounting costs by installing a Murphy. It will enable you to cut the coal bill and solve the labor problem. Only a short time is required to make the savings pay for an installation.

Send for Catalog HM-6. It will show you where you can save.

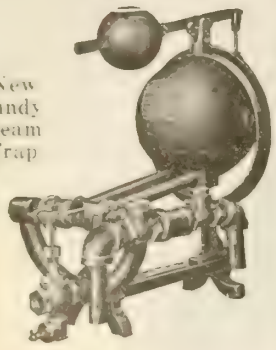
BURN ANY FUEL THAT HAS HEAT IN IT

DON'T EXPERIMENT!



New Bundy Steam Trap

The splendid reputation of Mason Power Plant Devices is not the result of an accident, but the expected outcome of thirty years of persistent effort backed by large capital and superior manufacturing facilities.

They hold the first place to-day because their merits entitle them to that position.

No other devices work so accurately, wear so long, nor accomplish their purpose so fully as the Mason. Once installed they are always demanded thereafter, and thousands of manufacturers absolutely depend upon these devices working in many critical locations and find them satisfactory.

Mason Equipment is designed by expert engineers of long and varied experience and having a full and complete knowledge of the requirements of a power plant, and they are built under the supervision of experts.

At The C.A.S.E. Convention

Our Toronto manager, Mr. S. Balmfirth, will be in charge of our exhibit.

Mr. Balmfirth is a practical engineer, having had charge of some important power plants before coming with our firm. Engineers will appreciate the fact that our Salesmen and Executives are practical engineers who sell from KNOWLEDGE of the application of our products to actual conditions, and not from catalogues.

Mr. Balmfirth will be pleased to discuss any Power Plant problems with the many engineers visiting the Convention. Engineers with problems in pressure regulation, pump or engine control, Feed water heating, regulating or filtering, condensation drainage or return, are especially invited to visit our exhibit.

COAL! THE FIRST STEP TO SAVE IT.

IN a series of tests made by eminent mechanical engineers, it was shown conclusively that 10% to 40% of the heat units of coal are lost, due to leaky boiler settings that allow an excess of air to enter the furnace or combustion chambers.

BETSON'S REG. U.S. TRADE MARK PLASTIC FIRE BRICK PAT. OFF.

Makes it easy for anyone to mould into place a solid, one-piece, monolithic boiler setting lining that is jointless, airtight and capable of withstanding the stress and strain because expansion and contraction have been neutralized.

With air tight linings and gas tight baffles, you may not only save the 10% to 40% of wasted heat units, but also reduce your repair and upkeep costs.

Betson's Plastic Fire Brick linings outlast other linings, not only because of high quality and experienced compounding but for the very logical reason that in the one-piece lining there are no bricks to work loose or joints to open up.

A pamphlet showing how to use Betson's Plastic Fire Brick is yours for the asking

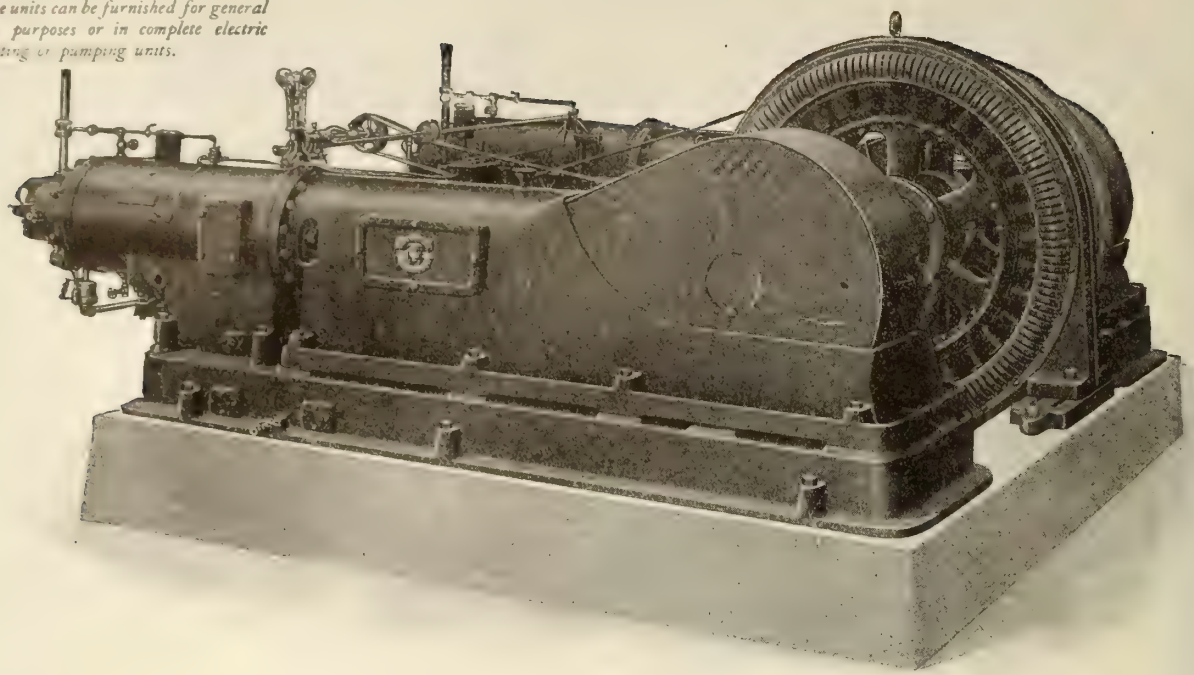
Giant Oil Engines are built in capacities from 12 to 200 H.P., both single and duplex types, also for operation on gas. Engine units can be furnished for general power purposes or in complete electric generating or pumping units.



Power for the factory— Electric current for the isolated district

ISOLATED mill and factory owners are installing Giant Oil Engines larger than necessary for their plant requirements and utilizing the surplus power for operating an electric generator—thus permitting the very profitable sale of electric current for private or municipal lighting.

Under this plan a Giant Oil Engine pays for itself in a surprisingly short time—then throughout a long service life pays big dividends on the investment.

Giant Oil Engines assure low fuel costs. They burn the lower grades of low-cost fuel oil. Their automatic regulation under all loads prevents power waste and eliminates the human factor in obtaining highest operating efficiency.

Giant Oil Engines are dependable. They are ruggedly constructed—free from all valves, magnetos, carburetors and other trouble causing devices.

Performance records of Giant Oil Engines operating under service conditions similar to yours are available.

Expert engineering counsel without obligation. Ask for Bulletin.

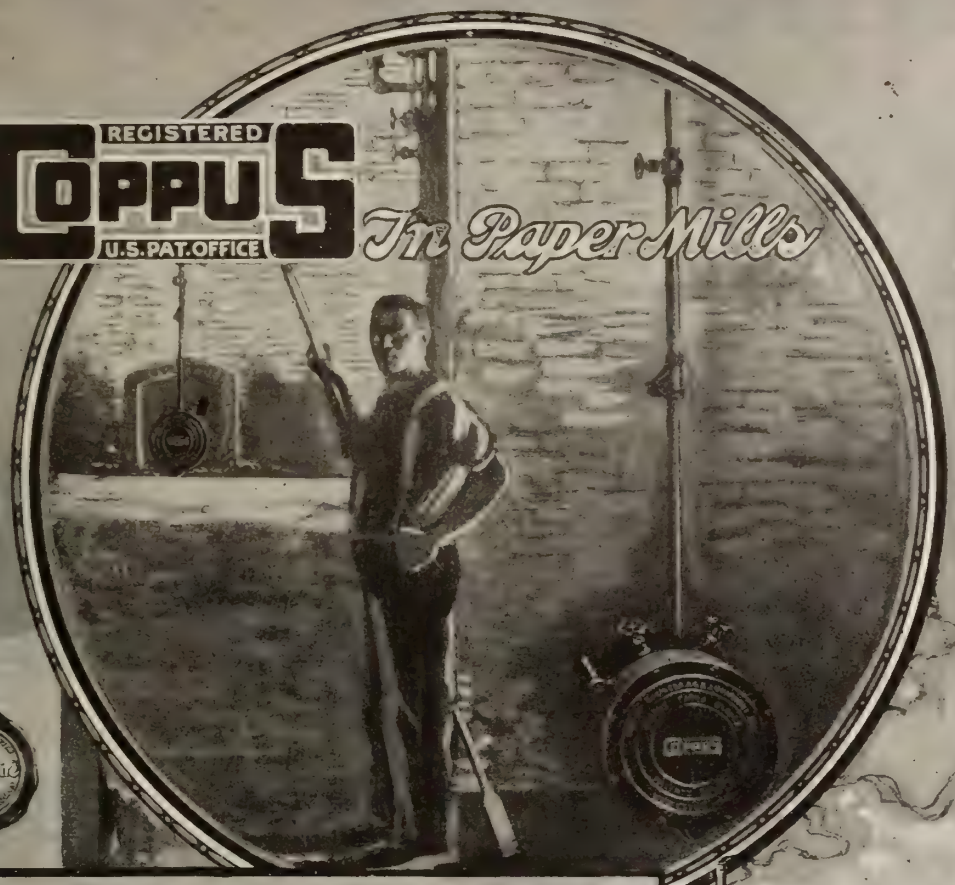
In Paper Mills



Old Hampshire Bond

STEADY steam pressure is a vital factor in making good paper. A sudden drop at the gauge might mean serious loss in the mill. Keeping up steam is a matter of prime importance.

That is why modern paper mills are equipping their power plants with COPPUS Turbo Blowers to maintain constant steam pressure under varying conditions of load, fuel, and weather.

For instance, the COPPUS Blowers shown above operating in the plant of the Hampshire Paper Company, makers of good paper, at South Hadley Falls, Mass., have kept steady steam pressure with very satisfactory results. Peak loads are quickly met, steam pressure is always constant, and cheap fuel is economically burned.

COPPUS Turbo Blowers are helping out engineers and speeding up boilers in power plants the country over. Their good work is not confined to the paper industry—it extends wherever power is used and coal is burned. If they are not already working for you it is likely that they could save time, money and labor in YOUR boiler room.

Write for Blower Catalog.

Mechanical Refrigeration

Reliable--Beneficial

THE many benefits common to all users of MECHANICAL REFRIGERATION, should make it a valuable adjunct to **your** business.

The uniform temperatures it provides have a better holding effect on the product in storage than ice, because the temperature produced by ice is not uniform, varying with the amount of ice in the refrigerator.

MECHANICAL REFRIGERATION permits the maintenance at all times of any temperature desired in the refrigerators or cold storage rooms, whereas you can not always get ice just when you need it, and a delay of a few hours often means a loss through deterioration of the product in storage.

If interested in MECHANICAL REFRIGERATION, a request for information and prices will receive our prompt attention.

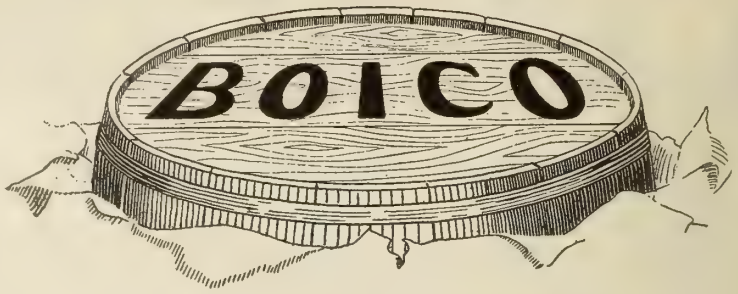
The Safe and Certain Boiler Cleanser

PUT a barrel of BOICO in your boiler room. It's the most efficient and economical **clean-boiler insurance** you can adopt. BOICO routs the most stubborn cases of boiler scale formations quickly and thoroughly.



Hundreds of Plants are Using BOICO Every Day With Unqualified Success

What BOICO will do in one plant it will do in another—**it will do in yours.**
BOICO loosens and brings away the hardest of old formations and keeps new scale from gathering. Yet it never does the slightest injury to boilers, valves or packings. Neither does it carry over in the steam, nor cause foaming or priming.

We are confident that BOICO will live up to all our claims and are prepared to let you test it FREE of cost. You have nothing to lose by trying it—let us hear from you.

Anti-Clinker Shell Bar Grates

There's no coal waste where these grates are used. Maximum air-space provides for perfect combustion. No clinker formation here, and you get more heat with less fuel.

One-Piece Jointless Furnace Lining

Why shift the blame on your engineer or fireman when it is your furnaces that are not up to the highest point of efficiency? USE PLIBRICO—it lasts longer than fire brick and is easier to instal.

Tip-It Patent Welding Process

With TIP-IT you get tools with shanks of carbon and tips of high-speed steel.

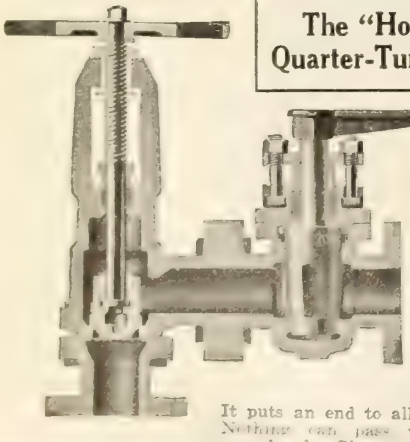
Ends Blow-off Troubles

The "Homestead" Quarter-Turn Valve.



An absolutely reliable combination consisting of the "Hovalco" Blow-off Valve and the "Homestead" Quarter-Turn Valve.

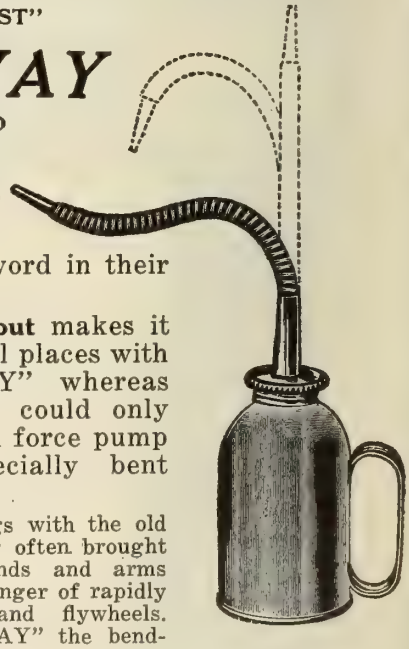
It puts an end to all blow-off troubles. Nothing can pass when both valves are closed. Gives a clear, straightway passage when open—no tendency to clog from scale. Write for full description.

Homestead Valve Mfg. Company

Pittsburgh, Pa. Works: Homestead, Pa.

"SAFETY FIRST"

ALL-WAY RAILROAD OILERS



are the latest word in their line.

The **flexible spout** makes it possible to oil all places with one "ALL-WAY" whereas previously they could only be reached with force pump cans with specially bent spouts.

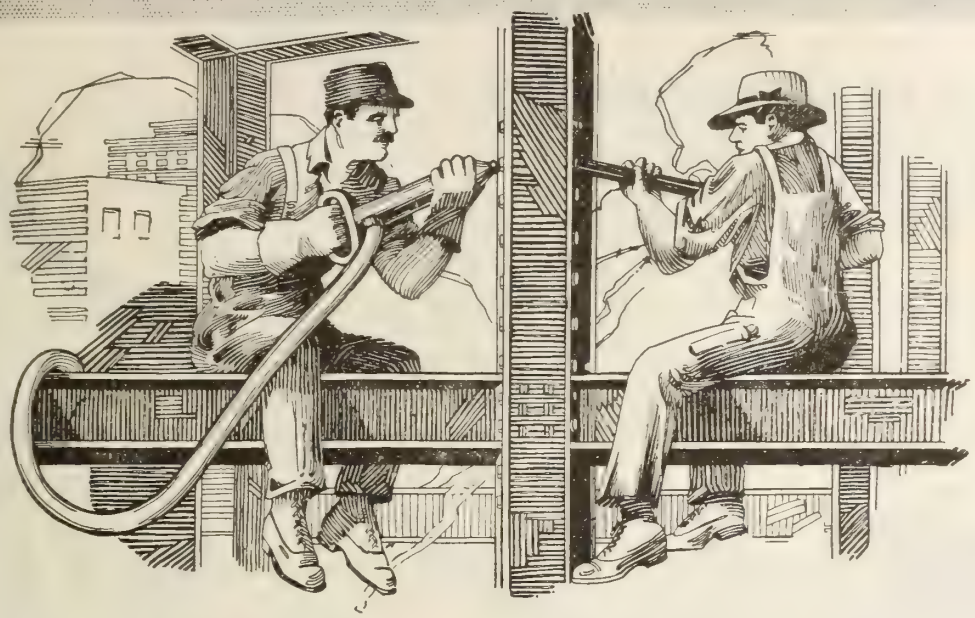
Lubricating bearings with the old straight spout oiler often brought the engineer's hands and arms very close to the danger of rapidly revolving gears and flywheels. With the "ALL-WAY" the bending of the spout removes this danger. Sizes No. 4, 1 pint—10 in. spout. No. 5, 1 quart—11 in. spout.

If your dealer cannot supply you write us.

We also manufacture the well-known "All-Way" Oil Can—saves you 50% of your oil bill.

THE ALL-WAY OILER MFG. COMPANY

196 KING STREET WEST - TORONTO, ONTARIO



The Policy Behind the Goodyear Cord Tire Built This *Better* Hose

MORE motorists would not be riding on Goodyear Tires than on any other brand, if Goodyear scientists had been satisfied with orthodox methods of tire building.

Neither would Goodyear Industrial Hose possess the qualities that enable it to give longer, more satisfactory service, if old-fashioned methods had been followed in its construction.

Modern industry's methods were studied exhaustively to ascertain the conditions industrial hose must meet in use. Then new formulae were created, new and more exacting standards set—resulting in a better hose, capable of standing up under the severest service.

The long service given by Goodyear Air Drill and Goodyear Pneumatic Tool Hose in mines, quarries, shipbuilding yards and structural work—where it is dragged over rocks and steel girders, beaten by ore and building materials—is evidence of the thoroughness of construction of all Goodyear Industrial Hose.

The cover on any air drill or pneumatic tool hose is prominently responsible for the life of the hose. The extra-heavy cover of tough, white rubber on Goodyear Air Drill and Goodyear Pneumatic Tool Hose resists wear and greatly prolongs the life of the hose.

Inside this hard-wearing cover is a special, oil-resisting inner tube, and a fabric of such strength that five-ply is found as satisfactory as six or seven-ply of old-style hose.

Records of Goodyear Air Drill Hose giving from 18 months to 2 years' service are in our files. We have similar records of long, satisfactory service and lessened hose costs, due to the use of Goodyear Industrial Hose in other classes of work.

Let a Goodyear man specify the particular kind of Goodyear Industrial Hose that will lessen hose costs in your plant. No obligation. Phone, wire or write the nearest branch.

The Story in a Nut-shell—

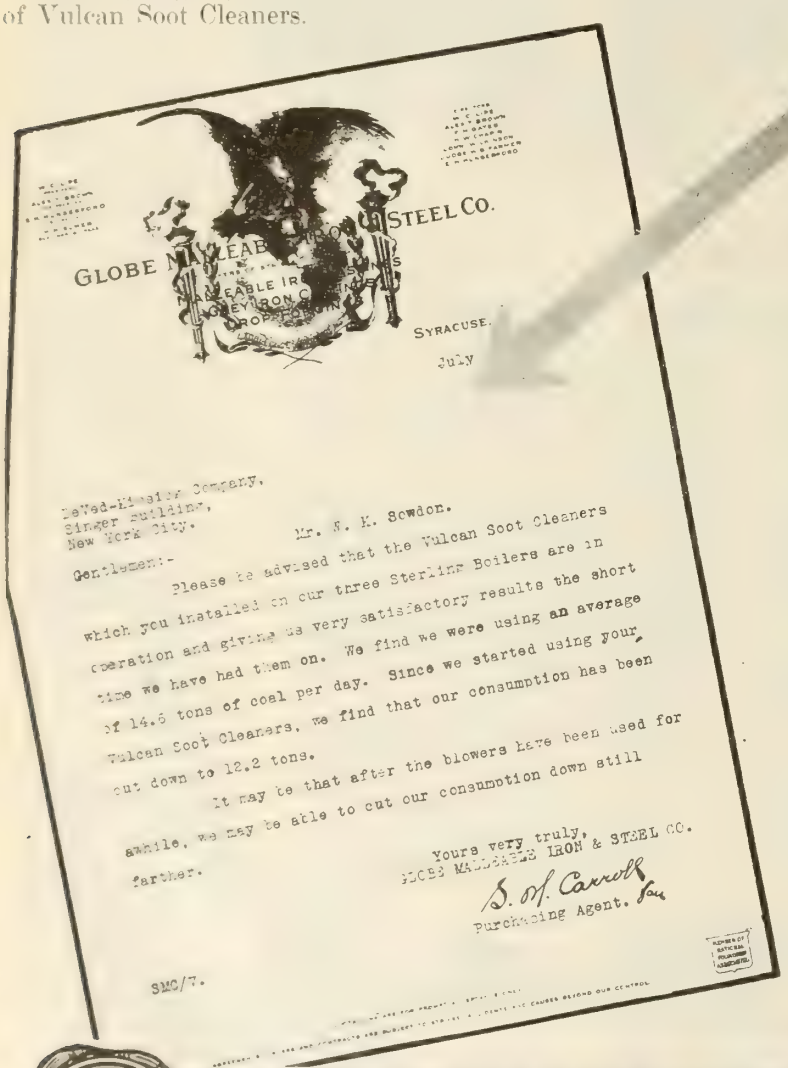
JUNE 11th: Received order to equip 2—250-hp. Class E22 Stirling Boilers and 1—125-hp. Class E11 Stirling with Vulcan Soot Cleaners. Steam pressure 110 lb., soft coal burned, hand fired.

JUNE 25th: Three Vulcan Soot Cleaners shipped from DuBois to Syracuse by express.

JUNE 30th: Vulcan Soot Cleaners arrived in Syracuse.

JULY 4-5-6: The three Vulcan Soot Cleaners COMPLETELY installed in three days.

JULY 29th: Received letter reproduced below from Mr. S. M. Carroll, Purchasing Agent, claiming fuel saving due to the installation and use of Vulcan Soot Cleaners.



GLOBE MALLEABLE IRON & STEEL CO.

SYRACUSE.

July

DeWed-Kingsley Company,
Singer Building,
New York City.

Mr. F. K. Sowdon.

Gentlemen:-

Please be advised that the Vulcan Soot Cleaners which you installed on our three Sterling Boilers are in operation and giving us very satisfactory results the short time we have had them on. We find we were using an average of 14.6 tons of coal per day. Since we started using your Vulcan Soot Cleaners, we find that our consumption has been cut down to 12.2 tons.

It may be that after the blowers have been used for awhile, we may be able to cut our consumption down still farther.

Yours very truly,
GLOBE MALLEABLE IRON & STEEL CO.
S. M. Carroll
Purchasing Agent.

SMC/7.

2.4 Tons of Coal per day —SAVED— by Vulcan Cleaners

Just suppose this had been YOUR plant, instead of that of the Globe Malleable Iron & Steel Company.

You know your daily fuel consumption—figure it out for yourself.

And this might well have been your plant. For time has demonstrated that the reliable VULCAN, operating on Stirling Boilers, is practically 100 per cent. THOROUGH—and it stands to reason that what it can do in one plant it ought to be able to do in another to a greater or less degree, depending upon conditions.

To be sure, we do not claim that the Vulcan Cleaner will absolutely produce as high a saving for you as it has for the Globe Malleable Iron & Steel Company. That would be an exaggerated claim—and it is the consistent VULCAN policy not to exaggerate. We emphasize this case merely to show the great possibilities of the efficient Vulcan Cleaner.

What we do claim, and we can back this up with evidence from practically every state in the union, under practically every condition of operation, is that the installation of Vulcan Cleaners on your boilers will produce a fuel saving more than enough to pay for the installation in the first year, and a worthwhile profit thereafter.

Ask for full Vulcan Data

You will be interested in the Vulcan method of removing soot from Stirling Boilers—ask for further information. Also, note that we make cleaners equally as efficient for all other types.

Woodstock the Scene of C.A.S.E. Convention

A Little Chat About the Town, Its Surroundings, and Industries, with a Brief Description of the Interesting Water Works System.

T. H. FENNER

WESTERN ONTARIO has again been successful in securing the convention of the Canadian Association of Stationary Engineers, and the precise location is the city of Woodstock. Here preparations are already under way to ensure that everything will go with a vim, and that the success of the convention at Brantford will be no whit greater than the one to be held by its smaller neighbor.

Woodstock, itself, is a city of industries, surrounded by some of the finest dairying and agricultural country in the whole Province of Ontario. The country round about is of the type known as rolling, and is pleasantly wooded. From a number of points just outside the city some wonderful views can be obtained, miles of green fields, woods and hills stretching away till they finally meet with the distant horizon. Seen from these vantage points, the city itself seems to have been set in the midst of a forest, the effect being produced by the number of shade trees in the streets.

The Early Settlers

Woodstock was somewhat of an aristocratic centre as far as its early settlers were concerned. These were mostly retired British naval and military officers, and their names are perpetuated to-day in the streets of the city. Vansittart Avenue, is for an example, named after Admiral Vansittart, one of the earliest settlers of the city. It is close on one hundred years ago since he came, so that Woodstock can lay some claims to having a history. Light Street, is named after an officer of the other arm of defense, in which he was a colonel. Another early settler was Admiral De Blaquier, whose grandson Lord De Blaquier, is at present living in England.

However interesting these old worthies may be from an historical point of view, there is something more up-to-date in the personality of Col. Joseph Boyle, whose home is also in Woodstock. Col. Boyle is perhaps better known as "Klondyke Boyle," and his services in the late war are such as to give every Canadian a thrill of pride. His achievements would fill a good sized volume, especially that part of them which took place in Russia.

Situated just on the outskirts of the city is the Woodstock College for boys, which is affiliated to McMaster University, Toronto. The college stands in the midst of wide grounds, and is a noted feature of the countryside.

The Industries

Although almost entirely surrounded by agriculture, Woodstock itself is as we have said, an industrial centre.

The Leading Firms

The main lines of manufacturing carried on are woodworking, textile and milling. The plants are mostly taking hydro-electric power to some extent, some running on this entirely. The woodworking factories include furniture making, piano making, and veneers. The textile factories make chiefly knitted goods. There are also one or two machinery firms. The names of the leading firms are as follows:—The Bain Waggon Co., making heavy wagons, such as are familiar to most of us who have seen them carrying loads of stone, gravel, etc. The Canada Furniture Manufacturers, who have a large plant, which is not run to full capacity at present, due to shortage of labor. The Thomas Organ Co., and the Kahn Piano Co., make as their names would indicate, musical instruments. Among the textile makers are the Harvey Knitting Co., Hosieries Ltd., Oxford Knitting, Sterling Textile Co., The Whitelaw Engine Company, and the Concrete Machinery Co., represent the heavy trades. The Peerless Cereal Co., Thos. Cullen & Sons, Westlake Confectionery Co., Hay & Co., Standard Tube Co., Bruthaup Leather Co., Crown Lumber Co., all represent important lines, while the James Stewart Manufacturing Co. look after the stove manufacturing industry. Power is cheap, though not as plentiful as could be wished. As in many Western Ontario towns, most of the people own their own homes, and are thus practically permanently settled. This feature of course insures a very steady labor market for the various firms in the city. Railway communications all over Canada are made by both Grand

SOUTH PARK AND PUMPING STATION.

Trunk and Canadian Pacific lines, while Ingersoll is also connected to Woodstock by an inter-urban electric line, 10 miles long. It is about two and a half hours distant from Toronto, and is in easy reach of Paris, Brantford, and London. The population is about 10,000.

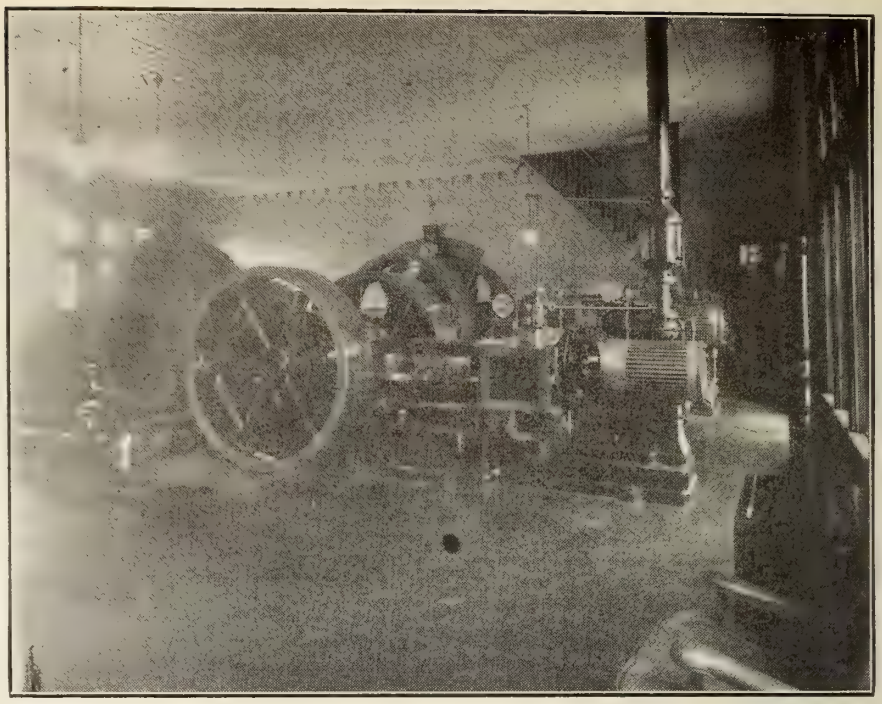
The South Side Park

There is a very pretty little park laid out on the south side of the town, surrounding the waterworks pump house, and the Ontario hydro electric station. There is a small lake on which boating is indulged in, and a pavilion is also provided, in which band concerts, etc., are given. The park is largely used during the warm weather as a picnic ground by the population, and for such a purpose is very well suited. Those attending the convention will no doubt spend a good portion of their time in this pleasant spot, especially if the weather is warm.

The Woodstock Waterworks

We have mentioned the pump-house standing in the park, and a description of the waterworks system will no doubt be of interest to readers in general, as well as delegates to the convention. The system is unusual in some ways, as the water supply is wholly derived from springs, which deliver the most delicious, cold and translucent fluid that man could desire. It is perhaps not all it might be for boiler feed purposes, but for drinking water it is ideal.

The works date back to 1880, when they were first built by private owners. In these days the works were used only for fire protection purposes, and the people secured their drinking water from wells. This condition obtained until the year 1885, and at that date there were approximately 6½ miles of mains, and about 60 hydrants. At this date the town took over the existing plant, and the present system was constructed, being completed in 1892. The site chosen for the pump house was on Cedar Creek, and here enough land was bought to make the present park, about eight acres in extent. The engineer in charge of the station also has a house on the property, the house being of course owned by the city, and retained for the use of the engineer.



TANDEM COMPOUND ENGINES.

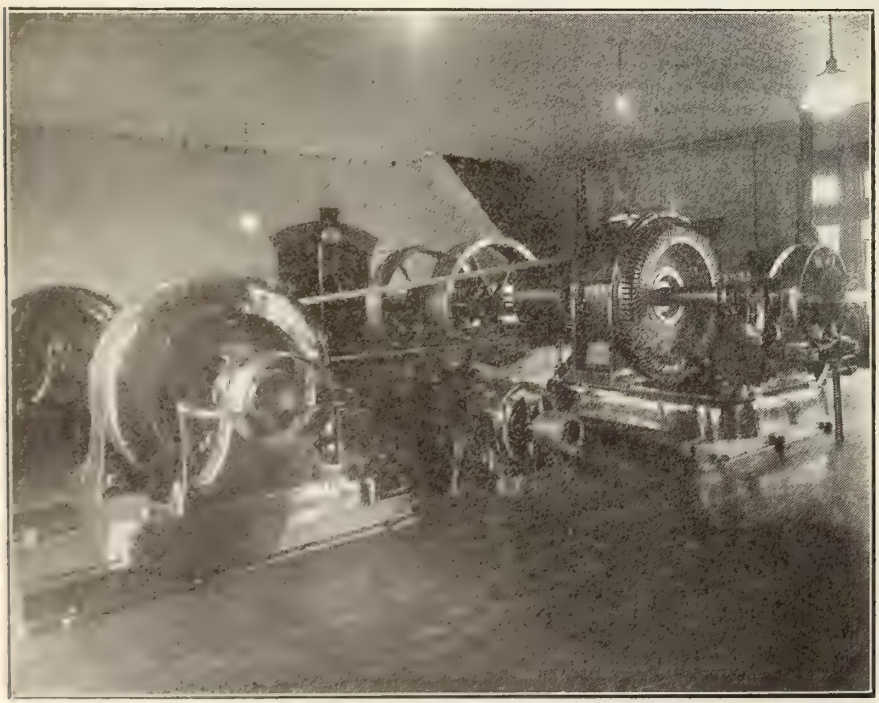
The Pumping Station

The pumping station is a one storey brick building, with concrete floors, slate roof, and masonry foundation. It is divided up into pump room, boiler room, store room and coal bunker. Originally it was equipped with horizontal return tube boilers and steam pumps, but this was discarded, and replaced by more modern units.

The present equipment consists of a compound duplex high duty reciprocating pump, built by the John Inglis Co. in 1908, and having a capacmity of 4,000,000 gallons per day. This pump is now used only as a stand-by unit. The daily work of the station is carried on by two 8-inch centrifugal pumps of the Mather & Platt design, built by the Canadian Allis Chalmers, and driven by direct connected induction motors. These were installed in 1911.

Steam is supplied by two 220-H. P. Babcock & Wilcox boilers, one of which is kept under banked fires with 50 lbs. steam pressure always handy, in case of emergency.

The electrical equipment consists of a Canadian General Electric Co. synchronous motor of 470-H. P., 25 cycles, 2300 volts, running at 500 R. P. M. This supplies power to the 2-200 K. W. revolving field, C. G. E. generators, and also acts as a power factor corrector. The power is taken from the hydro lines at 13,000 volts into the station, and it then transformed to 2,300 for power and distribution purposes. Power is also supplied from the Hydro through the station switchboard for factory purposes, the limiting amount being 1250 K.W. There are two switchboards, one being the incoming board from the Hydro, and the other of six panels, being used for distribution purposes.



SYNCHRONOUS MOTOR AND GENERATORS.

Steam Power

There are besides two steam engines, both of the compound tandem jet condensing type, but built by different mak-

VIEW OF SWITCHBOARDS.

ers. One is by Leonard & Son, London, the Peerless; while the other is a Mansfield engine. The Leonard engine is used in the winter to relieve the peak conditions, and is a great saving to the town by this means, bringing the maximum peak load down considerably. There is a condenser built by the Stillwell Pierce & Smith Vaile people.

The station is kept in such condition that it is a pleasure to look at. The Hydro Electric Commission have a substation in the rear of the pumphouse which possesses features of interest to those interested in the electrical field, especially of the high tension variety.

The Receiving Well

Just behind the pump house is a well in which the conduit that conveys the water from the spring is delivered, and the pump suction draws from. The conduit which brings the water from the springs is 17,600 feet long and is made for the most part of vitrified pipe, excepting at certain portions where cast iron pipe has been installed. These places are where depressions occur in the line, and in order to avoid air pockets, breathers have been installed, which are brought up to a little above ground level.

The Springs

The springs that supply Woodstock with its clear, beautiful water, are situated some three miles out of town. They are three in number, known as the Hart springs, the Cormac Thornton group, and the Webster-Thornton group. The total flow is about 4,000,000 galls. per day. The source of these springs is unknown, but it is surmised that they come from a considerable distance. This opinion is based on the fact that neither flow nor temperature vary to any appreciable extent at any time of the year. The main groups are the two last named, and the ground surrounding these to the extent of about 150 acres has been acquired by the city. A farm house is on the land, and the tenant is supposed to keep an eye on the ground and prevent trespassing. These grounds are kept strictly private, everybody but the necessary officials and workmen being rigidly excluded. This is of course to guard against the development of insanitary conditions. It is somewhat unfortunate that this must be so, as the situation is one of extreme beauty, well wooded, and the floor covered with all kinds of wild flowers, which the rich moist soil encourages, the whole area is traversed by the small streams which flow like veins to the main basin. In order to guard against the irruption of surface water, a protecting ditch has been carried practically all around the property, which effectually drains the surrounding land. All these small water channels have been thoroughly cleaned, and many of them are paved. The settling basin itself is of concrete, and at its lower end a screen is provided, to intercept any matter floating on the surface. The water which goes down the channel below the screen comes up from underneath and through a set of horizontal screens, after which it runs down to the house which covers the end of the main conduit and the valves for closing off the supply. In the settling basin there is also a flushing arrangement, and by dropping a gate into a weir at the upper end, the basin can be closed off, and the water be passed. The settling basin can then be emptied, and cleaned out, and this operation is performed at regular intervals.

In walking around the grounds observing these springs, the writer came across a mechanical apparatus rarely met with. This was a hydraulic ram, which supplies the farm house and barn with water, year in and year out, and as far as could be ascertained, with little or no attention. This is one of the earliest forms of pumping apparatus, and employs the kinetic energy of flowing water to raise itself to a higher level.

The Reservoir

Leaving the springs regretfully, for the spot was certainly one in which it was pleasant to linger, we proceeded to the reservoir. This is situated high

VIEW OF CENTRIFUGAL PUMPS.

A Discussion of the Uniflow Steam Engine

A Paper Read Before the Manchester (England) Association of Engineers, by Mr. Henry Pilling, M. I. Mech. E., Goes Fully Into the Principles of This Engine.—Part II.

THE next interesting matter to consider is the cylinder. Experience appears to have resulted in a uniform practice of placing the inlet valves in the cylinder heads. This is advantageous to economy on account of the reduced clearance volumes and clearance surfaces, but the practice makes withdrawal and inspection of the piston and of the cylinder interior more difficult. Designers may with advantage consider this point. There are some very interesting constructions in existence which show great ingenuity. For example, observe the sketch—Fig. 9—of a jacketed double cylinder cover. The design is a continental one. Fig. 10 represents a cylinder of a "Uniflow" engine designed by the author. It has a built-up cylinder, a bolt reinforcement across the otherwise weak exhaust belt and an access door—Fig. 11—whereby in large sizes a man obtains access to the cylinder, and in small sizes makes his inspection by means of a periscope. The design may be usefully studied from another point of view. "Uniflow" cylinders, when in work, are hot at the ends and cool in the centre. If the cylinder is originally bored parallel, then in work the cylinder would be come a double cone and the piston and rings would suffer. In practice, therefore, the cylinder has to be bored with a double taper, so adjusted that when working temperature conditions obtain the cylinder is parallel. The amount of correction required has to be computed. In a large cylinder, say 60 in., the correction will be about ⅛ in. in diameter at each end.

Pistons

Closely connected with this matter of diametral change is the piston, which is also subject, though in different kind and degree, to diametral alteration. It is easy to see that the piston will be hot at the ends and cooler about the centre. Hence the piston also requires turning double taper, in order that it may be as nearly as possible a true parallel cylinder when at work. It should also be easy to observe the rule—though some makers have let themselves in for quite avoidable trouble by a failure to note the point—that under any or all circumstances, even the worst, i.e., a hot piston in a cold cylinder, the piston must have clearance.

Next, owing to the long piston-rod and cylinder peculiar to the "Uniflow" engine a back piston-rod support in large engines is useless. Deflection of the rod would be too great. The piston must therefore be carried on the cylinder bottom. This important *main slide* requires care in design and manufacture.

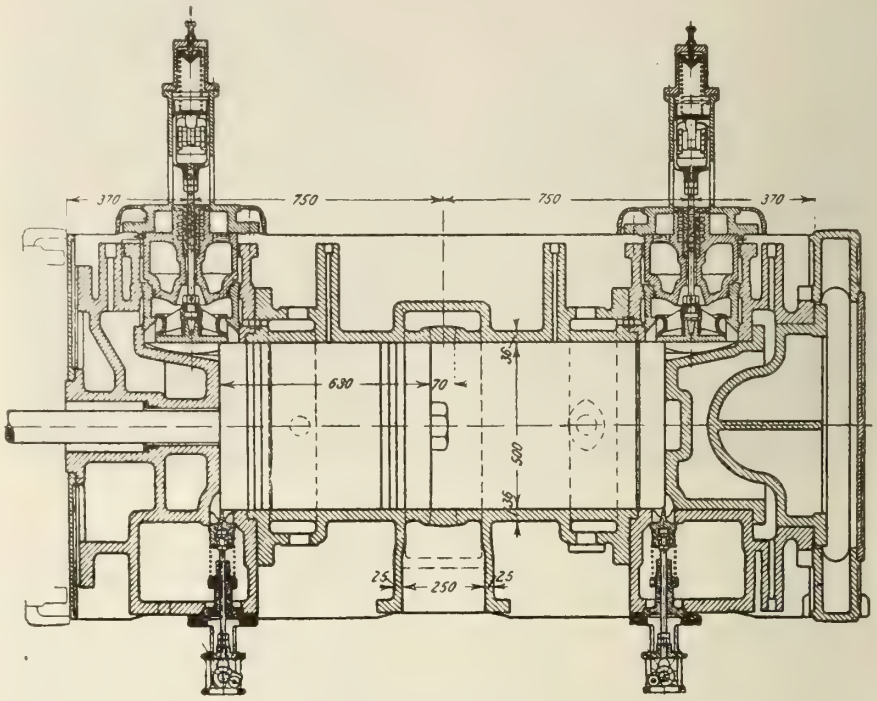

FIG. 9

Item 1.—Piston must be straight and not barrelled when working. Cylinder must be straight and not barrelled when working. Otherwise correct contact is impossible.

Item 2.—Piston diameter must be less than cylinder diameter to prevent seizing. The lower third of the piston must bed truly on the cylinder, otherwise line contact only takes place, followed by wear and tear and risk of overheating.

The two difficulties are met in small engines thus—the first one by suitable boring and turning during manufacture; the second one by turning the piston or the shoe thereon in two operations, *i.e.*, turning the shoe part to the exact expected hot cylinder diameter, and all the rest of the piston to the desired clearance diameter. For large pistons, however, I do not regard this as entirely adequate. For example, in the 60 in. cylinder 6 ft. stroke which I have cited, the piston is about 5 ft. 6 in. long. Owing to changes of working load, changes in steam pressure and superheat temperature, it is certain that the bottom of the cylinder will never consistently be a dead true straight line, nor will the piston be straight. This would mean point or line or shifting contact with resultant wear and risk of heating.

My mental processes in designing this piston started with the inquiry, "*How* can I make certain that the weight of this heavy piston—about 5 tons with its rod—shall be distributed on the cylinder bottom in such manner that the pressure

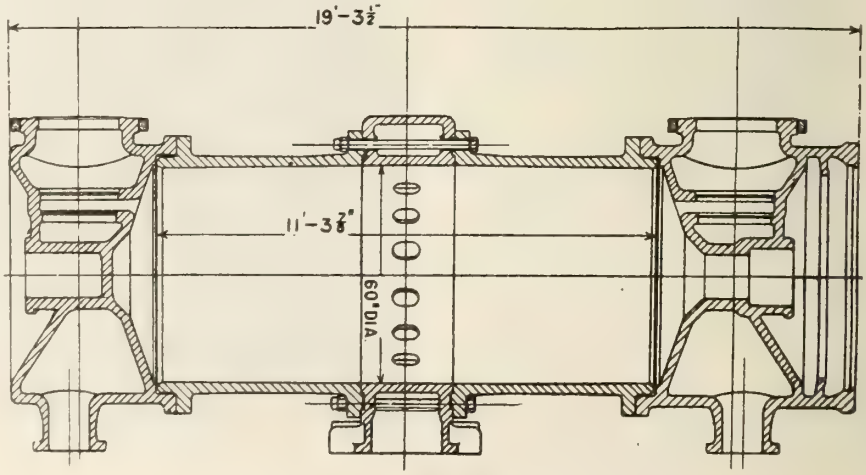

FIG. 10

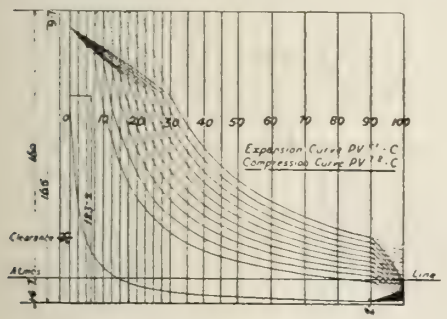
per square inch is *absolutely uniform* and constant, no matter how the cylinder or piston may vary in diameter, and no matter how the piston may tilt or settle fore or aft."

The next mental step was to realise that some method of articulation might meet the difficulty. The next to conceive the piston as having five flexible fingers or five flexible feet capable of sliding comfortably up hill or down hill without any one losing contact. The next to sketch and re-sketch alternatives until in actual fact six flexible shoes as shown on the drawing—Fig. 11—were duly incorporated. The piston heads are separate, and each separately held against a collar which takes all the load, while the connection is secured by a nut which takes *no steal load*. This makes for safety, and it may fairly be claimed that the piston cannot work loose. Longitudinal expansion and contraction of the piston-rod in the part between the two piston discs cannot cause any straining. This is due to the chair or mainslide on which the piston is carried being not bolted to either of the piston discs. It is quite free to expand



Initial Pressure on Piston 165 lbs absolute

Steam per I.H.P. hour from Diagram lbs	Cut-off % of Stroke	Mean press. lbs per sq. in.	Press. at cut-off lbs. absolute	Press. at beginning of Exhaust lbs. absolute
10 77	7¼	33·5	148	12 44
11 34	10	40 9	145	16 65
11·96	12½	46 6	141	19 65
12 45	15	51 9	137	22·5
12 89	17½	56·5	133	25 2
13 35	20	60·8	130	27 96
13·84	22½	64 9	128	30 84
14 25	25	68 9	126	33 65
14 71	27½	72 8	125	36 67
15 13	30	76 6	124	39 67

FIG. 12

and contract on its own account. The clearance allowed at one end of the chair cannot cause knocking or wear, inasmuch as the horizontal springs at this end have sufficient strength to prevent motion. There is no usual barrel or cylinder connecting the two piston discs. Hence a man can get through the inspection door of the cylinder, drop *into* the piston, examine the cylinder, examine the shoe details and note whether or not the piston is remaining central in the cylinder. The condition of the piston rings can be noted by barring the engine round and bringing the rings in turn under the inspection opening. By depressing the rings observation can be made of the amount of wear, and so on. Access is practicable to each side

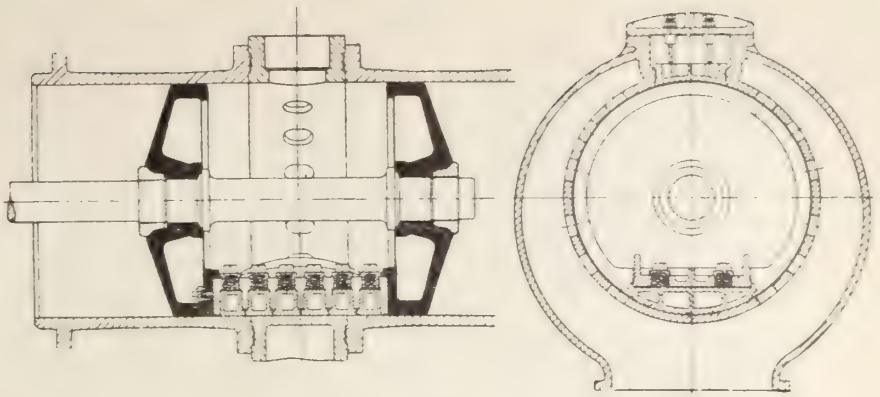


FIG. 11

of the piston right up to the cylinder heads.

Clearance and Compression

Attention requires to be given to the fact that a usual clearance in uniflow cylinders is about 3 per cent. for condensing conditions and 18 per cent. for non-condensing conditions. These assume about 1½ lb. and 15 lb.—absolute—back pressure respectively. If a 3 per cent. clearance condensing engine is at work under 1½ lb. condensor back pressure, the compression will rise at the end of the stroke to about 130 lb. For falling vacuum up to non-condensing working the compression would be as follows:—

Three Per Cent. Clearance

1½	lb.	Back	Pres.	= 130	lb.	Com. Pres.
3	"	"	"	= 260	"	" "
9	"	"	"	= 780	"	" "
15	"	"	"	=1300	"	" "

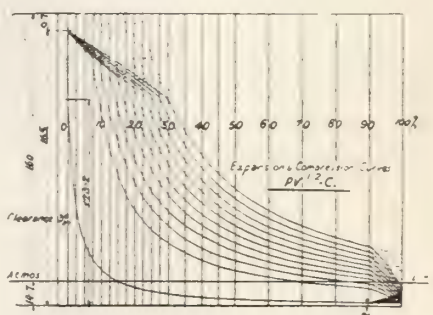
Clearly a falling vacuum is dangerous unless safety devices are provided. There are many attempted solutions from the ringing of bells to warn the attendant up to purely automatic self-acting relief devices. I prefer and advise the latter. Nothing else is safe. This also is fertile ground for inventors to cultivate.

Of course every condensing engine is—at starting—a non-condensing engine. The usual plan to ease the compression at starting where automatic devices are not fitted, is to open a by-pass valve, which admits the compressed steam to the interior of the cylinder cover. In this way the requisite augmentation of the clearance is obtained. The valve is closed after the vacuum is obtained. Reliance on maintenance of vacuum should not be carried too far. Ample relief valves are essential, but, as mentioned above, some form of automatic supplementary exhaust makes greatly for safety.

Indicator Diagrams and Steam Consumption

Inasmuch as "Uniflow" engines are substantially free from initial condensation losses, and as there are no complications due to the presence of receivers, as with compound engines, the following calculated diagrams—Figs. 12 and 13—will be useful.

The diagrams show clearly the nature of the expansion and compression curves, which will vary according to the circumstances of each particular case, *i.e.*, efficiency of cover jacket, efficiency of barrel jacket, if any, and so on. The diagrams must therefore be used with care. The good steam economy shown thereon can be readily obtained with care and skill. It can be lost for the want of it. It is known that different makes of engines have different efficiencies and economies, and that with the same maker even sister engines do not usually give similar results, and that as a rule the larger the engine the better the economy. No definite figure can be given here, therefore, to anxious inquirers. It is true here, as elsewhere, that usually the best engine is the result of unremitting care and attention to details, to observances of sound



Initial Pressure on Piston 165 lbs absolute

12 36	30	73 9	124	35 76

FIG. 13

theoretical principles, and to excellent workmanship.

As a matter of interest, two non-condensing indicator cards are given in Figs. 14 and 15. The first one is a "no

load" diagram. A third card, taken at a lower boiler pressure, and later cut off, is given in Fig. 16. The cards will repay careful study, special attention being given to the reduction in the mean average pressure by reason of the shape of the compression curve. The increased capital cost of the non-condensing "Uniflow" engine due to this fact is, however, more than balanced by the economical operating results obtained by the application of the "Uniflow" principle.

A comparison of the steam consumption of a "Uniflow" condensing engine with that of other engines will show that it is as low as in three-cylinder triple-expansion engines, and lower than in two-cylinder compound engines. More-

Fig. 14

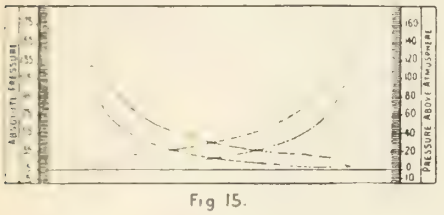

Fig 15.

FIGS. 14, 15, 16

over, this improved economy is attained not only in very large engines, but extends much in the same way as with gas engines, down to the very smallest sizes. Furthermore, the steam consumption per indicated horse-power per hour is more even over all loads between quarter and full load than with ordinary engines in which the steam consumption rapidly becomes unfavourable if the load on the engine passes either upwards or downwards from a very limited economical load region.

The Westinghouse Company have issued a catalogue dealing with their line of Watt-hour Meters. This is known as the Miniature Catalogue 3-A-1, and shows a great number of varieties of these instruments. A page at the beginning of the catalogue deals with ordering instructions, while on the inside back cover there is a list of Westinghouse agencies.

How Many Sizes of Shafting Should We Have?

IN ANSWER to the above query, the American Society of Mechanical Engineers recommend that fourteen sizes of transmission shafting be used. The committee of this society devoted to War Industries Readjustment, state that an immense amount of steel is continuously tied up in manufacturers' and dealers' stocks of shafting and that a corresponding amount of cast iron is also held in stock in the form of hangers, bearings, couplings, collars, bushings, pulleys, etc. At the suggestion of the chairman of the committee on War Industries Readjustment, a committee was formed to investigate the subject of the standardization of shafting sizes. The personnel of the committee is as follows: Cloyd M. Chapman, chairman; George N. Van Derhoef, Hunter Morrison, Louis W. Williams, and Russell E. Nelles.

This committee was confronted with two distinct but closely related problems, namely, standardization of the diameters of shafting used for transmission of power, such as lineshafts, countershafts, etc., and the standardization of the diameters of shafting used by machinery manufacturers in making up their product. The first of these problems seemed to be the simpler of the two. While a large number of sizes of transmission shafting are now listed and stocked, it was believed that comparatively few of these are in extensive general use. Accordingly, a letter was sent to thirty-six of the largest manufacturers and dealers in transmission shafting asking for statistics on the consumption of each size of shafting handled by them. About twenty of the largest concerns in the industry furnished complete statements of their sales over periods of time chosen by themselves. These data were reduced by the committee to a uniform basis of percentages. The amount of each size sold was expressed as a percentage of the total sales, both on a weight basis and on a lineal-foot basis. From these data, plotted in the form of a diagram, it was evident which of the sizes were popular and generally used and which were more rarely called for. A tentative list of twelve sizes was prepared from this diagram and sent to forty-six other dealers in transmission shafting and shafting supplies, from whom twenty replies were received.

In the letters to these firms, the committee expressed the opinion that the custom of using shafting 1/16 inch under the unit sizes is so firmly and so nearly universally established in this country, that it would be unwise to attempt to adopt sizes in even inches and fractions as standard. It was pointed out, also, that certain sizes stand out pre-eminently as "popular sizes" and that others are sold in relatively small quantities. It therefore seemed feasible to reduce the number of sizes now listed by the trade from fifty or sixty down to twelve or fifteen.

The response to these letters was practically unanimous in opinion. The transmission shafting users and dealers approved the plan of standardization, and the sizes suggested were generally approved except that the diameters 1 11/16 inches and 2 3/16 inches were in many cases requested to be included. After due consideration the committee decided to include these two sizes in the original list, making the fourteen sizes now adopted as standard.

Shafting Sizes Used in Machine Design

The second problem was a more intricate one. The number of sizes now produced by the rolling mills for use in machinery is very large. Almost every sixty-fourth of every inch up to three inches is drawn. If a reasonable number of these sizes could be eliminated or classed as "specials" and a comparatively few sizes selected as standard or stock sizes, a great saving would be effected. In order to get the opinion of leading consumers of shafting for machinery purposes, the committee decided to lay the plan before 225 large consumers of this material. It was explained that it was not intended that the adoption of certain sizes as standard should make it impossible to secure any other size required on special order.

In the case of machinery shafting the users were equally unanimous in their approval of the plan to standardize sizes, but recommendations as to size intervals varied greatly. However, these recommendations, in so far as they were definite and specific enough, were tabulated and a diagram constructed showing the relative popularity of the various size increments for each inch of diameter.

With these data accumulated and sifted down to usable form, the committee felt that it was in a position to present its information and preliminary deductions to representatives of other interested organizations. Accordingly, invitations were issued to twelve societies and associations requesting them to consider the proposed lists of standard sizes and to appoint representatives to confer with the committee before its report was finally formulated. The seven

organizations listed below responded, and the standard sizes which follow have the unanimous approval of these representatives and, as far as can be learned, of their associations: American Hardware Manufacturers' Association; American Railway Engineering Association; American Supply & Machinery Manufacturers' Association; National Association of Manufacturers of U. S. A., National Association of Purchasing Agents; National Machine Tool Builders Association; and Southern Supply & Machinery Dealers' Association.

Report on Shafting Sizes

On January 14 the committee submitted to the council a report in which it recommended the approval and adoption of the following lists of sizes as standard for the society:

Transmission Shafting—15/16, 1 3/16, 1 7/16, 1 11/16, 1 15/16, 2 3/16, 2 7/16, 2 15/16, 3 7/16, 3 15/16, 4 7/16, 4 15/16, 5 7/16, and 5 15/16 inches.

Machinery Shafting—Size intervals extending to 2½ inches, by sixteenth inches; from 2½ to 4 inches inclusive, by eight inches; and from 4 to 5 inches by quarter inches. The council approved the report and accepted the recommendations.

Troubles Caused by Moisture in Compressed Air

It is a Well-Known Fact That Moisture in Compressed Air is Something to be Avoided—The Discussion Explains How This Trouble May be Overcome

By F. A. McLean

MOISTURE in compressed air should always be avoided as much as possible, especially where it is to be used to operate reciprocating or rotating mechanisms on which it has a pernicious effect when carried into the working parts, tending to wash away the lubricant, thereby increasing the wear and shortening the life of the moving parts through leaving highly finished and closely fitted surfaces bare, and in sliding or rolling contact with each other. While this is true of practically all air-operated machines, it is particularly so in the case of those operating at high speeds, such as hammer drills, pneumatic tools, motor-driven air-hoists, sand rammers and the like, in which the surfaces exposed to wear are of necessity limited in size, and since air underpressure is hard to hold, the parts are machined to very close limits, and wear is particularly objectionable on the ground of lowered economy through increased air consumption and loss of power.

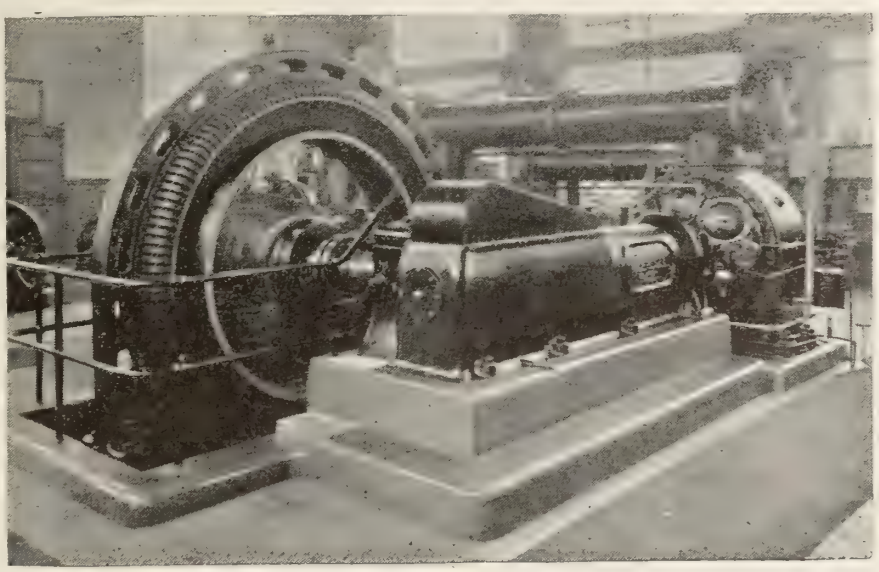

FIG. 2—MOTOR DRIVEN, DIRECT CONNECTED COMPRESSOR AND HORIZONTAL AFTERCOOLER. THE AFTERCOOLER IS DIRECTLY IN FRONT OF THE COMPRESSOR, AND NEAR THE WINDOW.

While moisture in wet air is bad enough in interior piping, its effects are likely to be far worse out of doors in open cut mining, quarrying, contracting, shipbuilding, switch and signal work, etc., where it is likely to collect at low points in the system, causing water hammer with consequent racking effect on the joints and loss of power through reduction of the air passages, as well as increasing the danger of freezing and bursting of the pipes during cold weather. The low temperatures caused by the rapid expansion of the air from the exhaust of rock drills, pneumatic hammers and other air-operated devices will often freeze the moisture, clogging the exhaust openings and preventing their efficient operation.

On railroad switch and signal work, freezing is a very serious matter, as, should these devices fail to function at the proper time through the freezing of the working parts, it is likely to cause considerable loss of life and property.

Time is generally an important factor in contracting and mining operations and losses in this respect are usually of more importance than in other directions. It is, therefore, essential that the proper precautions be taken to ensure freedom from interruptions which are too often caused by freezing of the pipe lines, drills or tools. In a case of this kind which came to the writer's attention late last fall, operations at a large Eastern mine were held up and the miners forced to sit around and "swap" stories for two hours while waiting for the pipes to be thawed out. This did not happen on a cold day, but on one that was damp and muggy.

While it is possible to compress air, it is practically impossible to compress water and sometimes breakage of the working parts of a tool is caused by too much water in the air lines. Pneumatic tools and other air-operated equipment are designed to operate on air and are not adapted for "hydraulic drive."

Where tools or drills are operated on air which contains an excessive amount of water and are then allowed to remain idle for a while without proper attention they soon get rusty and it is usually not long before losses from air leakage and maintenance costs grow larger.

The Importance of Cool Compressed Air

Air discharged from the cylinder of a compressor is hot in comparison with the atmosphere, and on entering the supply pipe lines heats them to some extent. this heating effect travelling further along the pipe lines with the continued operation of the compressor causes them to expand gradually, with the result that when the compressor is shut down for the night, in the cooler atmosphere, they are subjected to an equivalent, but more violent contraction. Although this effect may not be readily noticeable, it is likely to result in strained and loosened joints, with consequent loss of efficiency through leakage.

Aftercoolers—The Remedy

It is a well-known fact that atmospheric or free air always carries moisture (the amount varying with meteorological conditions in different localities),

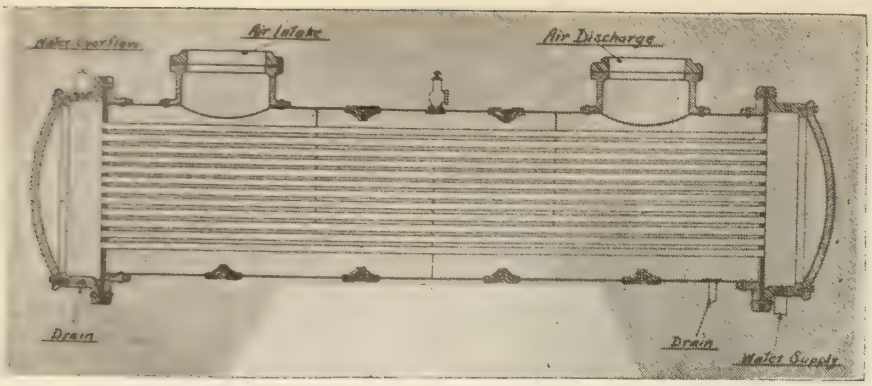

FIG. 1—DIAGRAMMATIC VIEW OF A HORIZONTAL AFTERCOOLER.

and that it also has the capacity to absorb more up to the time that its saturation point is reached.

The moisture carrying capacity of air increases rapidly with rises in its temperature and decreases, but not quite so rapidly with increases in pressure. As the pressure will always be at the highest point just as the air is leaving the compressor, if we can reduce its temperature to the lowest point, the air will be in a position to give up so much of its moisture that there will be little or none left to cause trouble when lower pressures and mayhap higher temperatures are reached further along the line. It is thus evident that the remedy for these conditions lies in reducing the temperature of the air after it leaves the compressor and before it enters the pipes, to as low a point as possible, which will not only prevent all of these troubles, but will ensure better all around distribution efficiency as a whole. Some cooling takes place in the intercooler of a compound or state compressor, and with the larger and better designed intercoolers used on modern compressors, more of the moisture is removed by this means than was possible with the older types. The air receiver also cools the air to some extent and serves as a receptacle for the collection of moisture from the air which passes through it, and for this reason is fitted with cocks by which the moisture can be drawn off at intervals.

In the simplest form of compressed air power plant, the receiver is the only means of removing moisture from the air that is employed. Too much reliance should not be placed on the receiver for this purpose, however, as when located close to the compressor as it should be and the consumption of air is heavy, the temperature of the receiver shell will usually be such that little or no condensation can occur. In some cases, the temperature of the receiver becomes so high that oil carried from the compressor cylinder becomes ignited, causing serious fires or explosions. It is, therefore, better to depend on some means of cooling and drying the air after it has left the compressor and before it enters the receiver and supply lines, and this is where the aftercooler "fits in."

What the Aftercooler Will Do

Aftercoolers cool and dry the air more thoroughly than is possible with the best type of receiver, and so reduce to a minimum the troubles which follow the use of wet air, and in addition remove some of the oil which might be carried into the receiver and perhaps to the pipe lines, to the detriment of the air supply hose. While of considerable importance in mining, quarrying and contracting, especially in tunnels and shafts where oil in the exhaust of rock drills or coal cutters tends to vitiate the air, clean air is even more of a necessity in the case of foundries or in wood-working and textile plants where the air is used for cleaning machinery, or spraying paints, varnishes and other finishes, and the aftercooler is of great value under such conditions.

One of the principal functions of an air receiver is to compensate for the pulsating effect of each stroke of the compressor piston and prevent rapid fluctuations in the air pressure. For this reason the receiver should have sufficient capacity to prevent any material rise in the receiver pressure by the volume of air forced into it at each stroke of the compressor piston. If the air is allowed to pass directly into the supply pipes, there will not be sufficient space for its immediate accommodation and the pressure will momentarily run up far in excess of the average pressure in use, accompanied by a periodic acceleration of flow. This results in an increase in the frictional resistance of the pipes and at the end of each stroke the compressor piston is required to force the air out of the cylinder against a pressure temporarily greatly in excess of normal, increasing the power consumption and putting an unnecessary strain on the compressor. In a single cylinder compressor the discharge pulsations are more violent than in stage compressors, as the total discharge must take place from a cylinder of larger diameter in a smaller portion of the stroke than is the case with the high pressure cylinder of a multistage compressor where the discharge valves open earlier in the stroke and the diameter of the air pipe is about one-half that of the cylinder. In this respect the installation of an aftercooler, since it increases the available receiver capacity, will be of considerable benefit, especially in intermittent work, such as running rock drills, pneumatic tools, hoists, etc., and will assist the governor

FIG. 3—TABLE SHOWING CAPACITIES OF INGERSOLL-RAND HORIZONTAL AFTERCOOLER.

or regulator of the compressor in maintaining a steadier pressure.

Aftercoolers usually consist of a cylindrical steel or cast iron shell with cast heads supported on cast iron foot pieces surrounding a nest of iron or brass tubes, the ends of which are either expanded or fitted with copper ferrules and caulked into steel tube plates at each end of the casing, provision being made for expansion and contraction. Water enters the lower set of tubes, traverses each row and leaves at the top of the shell, while the air enters and leaves at the top, surrounding the tubes in transit and travelling in a direction opposite to the water. Baffle plates are arranged so as to cause the air to cross and recross the tubes several times. An open funnel is generally placed in the water discharge to show the amount of water flowing and facilitate its adjustment. The moisture collected from the air is prevented from escaping with the latter by a plate in front of the air discharge opening.

There is some difference of opinion as to the respective merits of iron and brass tubes for this class of service. Brass is a better conductor of heat than iron, but on the other hand, galvanized iron tubes are usually rougher and present more surface to the air, so that there is probably little or no difference between them in cooling effect. Vertical aftercoolers are sometimes preferred on account of the smaller floor space which they occupy, but aside from this, there is no reason for using one style in preference to the other. While aftercoolers of different makes vary in minor details, the essential principles of all are the same and their construction will be more readily understood by referring to Fig. 1.

Aftercoolers are usually equipped with pressure gauge, safety valve, flanged pipe connections, water fittings and drain cocks. When properly designed and supplied with the requisite amount of water they will readily reduce the temperature of the air passing through them to within 15 or 20 degrees of the entering cooling water. The temperature and quantity of the latter required depends on the cooling effect desired. The following figures which are based on good cooling results with air at 80 to 100 pounds gauge pressure when compressed by a two-stage machine, will be found accurate for use with aftercoolers of the type described:

Temperature of Cooling Water	Gallons per hour per 100 cu. ft. of actual free air per min.
50 Degrees Fahr.	120
60 Degrees Fahr.	150
70 Degrees Fahr.	180
80 Degrees Fahr.	210
90 Degrees Fahr.	240

Aftercoolers are made in a number of different sizes, the capacity of which varies with the temperature of the cooling water, and whether the air to be cooled is obtained by single or multistage compression. This point will be seen more clearly by examining the table in Figure 3, giving the sizes and capacities of Ingersoll-Rand aftercoolers.

An aftercooler may be suspended from the ceiling or mounted on or under the floor, as may be most convenient from the standpoint of economy of floor space or ease in making the necessary connections. It should be placed between the receiver and the compressor and as close to the latter as possible. Pipe of amply large size should be used in making the necessary connections and care should be taken to provide piping by which the moisture may be drained off at intervals. It is good practice to make connections from the compressor to the aftercooler and from the aftercooler to the receiver, one or two sizes larger than that leaving the receiver, using reducers to make the actual connections if necessary. Elbows should be avoided, any bends that are necessary being made by giving the pipes a wide sweep.

In some localities water is scarce, and where this condition exists it is often possible to use the cooling water from the aftercooler for hot boiler feeding, increasing the efficiency of the plant and adding to its economical operation to some extent through the recovery of waste heat.

While an aftercooler will not eliminate all of the moisture from compressed air, the best results in this respect, especially in the case of large installations, being obtained by the use of an aftercooler in conjunction with a number of small secondary receivers or moisture traps (of which there are a number now on the market, one of the best known as the Stratton) placed at intervals along the supply lines, it will be found that in the majority of cases the aftercooler alone will dry the air to such an extent that the troubles due to wet air and the consequent inconvenience and low efficiency which follows, are entirely done away with.

In addition to this, the installation of an aftercooler often results in increased economy in power consumption with no outlay other than the cost of the aftercooler, the necessary connections and a moderate supply of cool running water. It is thus evident that the inclusion of an aftercooler when securing estimates on new compressed air plant, or the addition of one to a plant already in existence, is a subject well worth the attention of anyone desirous of obtaining the highest efficiency from their compressed air equipment.

MUNICIPAL AUTHORITIES INSPECT DIESEL ENGINES

The Council of Yorkton, Saskatchewan, have decided to send the Mayor, Mr. Gibson, Deputy Mayor, Mr. Moritz, and the electrical engineer, Mr. McNicol as a deputation to visit the plants of the Nordberg Manufacturing Co., at Milwaukee and the Busch-Sulzer Co., at St. Louis, to inspect the Diesel engines manufactured by these firms and also other points where these engines are in operation, before definitely deciding which engine shall be purchased for the municipal power plant.

This decision was the result of a lengthy and exhaustive discussion upon all phases of the question, the Council being unable to decide which engine was the most suitable for their requirements from the information it had been able to secure on the subject. Both engines have strong points in their favor but there are matters of detail, which can only be decided by a personal inspection and in conference with the executive heads of the firms in question. The Council was also agreed that the cost of a deputation was but a minor item on a deal of this magnitude and that this expense could be saved many times over by personal negotiation with the manufacturers.

From information previously secured the total cost of the 500 2-cycle Nordberg engine together with generator, was placed at $90,000 and the total estimated cost of the Busch-Sulzer unit together with generator, at $88,000. As the Busch-Sulzer unit is rated at 520 h.p. the final cost per horse power worked out in favor of the Nordberg machine, it being $165.14 as against $177.26 for the Busch-Sulzer machine after making altitude allowances.

Both engines are designed with a water-cooled piston, which eliminates danger of seizing, but the Nordberg piston is designed for use with a cross head, making for ease in connection and inspection of connecting rods and bearings, no dismantling being necessary to make adjustments of these. The system of lubrication also appears to be to the advantage of the Nordberg but to make a definite decision in a matter of such grave importance to the town all were agreed that both engines should be seen in actual operation, not only in the plants where they are manufactured, but also in plants where they have been in service for some years where much valuable experience can be got from users in regard to troubles experienced and efficiency of operation.

There are also such points as guarantees, terms of payment, elimination of exchange, assistance in erection and supervision, time of delivery, etc., which can be discussed to much better advantage on the ground, all of which will be gone into fully by the deputation. When all the facts of the matter have been secured by the deputation they will be laid before the Council as a whole and definite action will be taken.

The deputation will leave for the south on Friday evening.

The Norwalk Iron Works Company of South Norwalk, Conn., manufacturers of air and gas compressors, have now a Canadian sales agency with offices in Toronto. This is in the hands of the A. S. Leitch Company, Kent Building, Toronto.

Some Examples of Economiser Tube Failures

Extracts of a Report Dealing with Explosions of Economizers. These Are Comparatively Rare, But the Causes Leading to Them as Shown by the Report Are of Interest.

C. E. STROMEYER

THE question of safety of cast-iron economisers has unfortunately once more forced itself on our attention by a destructive explosion at Brighouse, the damage to surrounding property being very great. These cases are very rare, as will be seen from Table II., which summarises all the economiser explosions, 17 in number, reported upon by the Board of Trade since 1882. Only nine of these explosions, inincluding the present one, No. 2,470, were destructive, but unfortunately none of the enquiries into these mishaps have revealed their true causes. As will be seen shortly, very material facts about the Brighouse explosion were not mentioned in the Commissioners' report, even the thickness of the metal being omitted, and there are indications that equally important information about previous explosions was either not found by the surveyor or, if found, was kept out of the reports.

The curious point about economisers is that from a practical engineering point of view, economiser pipes should not fail and yet they fail frequently. In fact these failures are so frequent that they are by common consent looked upon as being wear and tear, and are only discovered, if at all, at the annual inspections, when information may come to hand that during the year a sheet of pipes has been blanked off, or a pipe renewed. The metal of economisers is sound, the thicknesses more than ample, the factor of safety being between 20 and 30, there is plenty of room for expansion and contraction, and the simple cylindrical shape of pipes compares favorably with the relatively much thinner and more complicated steam engine cylinders. Yet although these are subjected to innumerable reversals of strain, they hardly ever fail, whereas unreported failures of economiser pipes, occur almost daily.

The information contained in Table II. has been carefully summarised as to the numbers of pipe failures which were reported to have occurred previous to the several real explosions in such a way as to represent the annual failures amongst 10 economisers, aggregating, say, 1,000 pipes. A negligible number of failures occurred in the first two years, due no doubt to carelessness during erection; but from the second year, and, therefore, long before serious corrosion could have occurred, up to the twentieth year, there was a steady annual rate of failures of 2.2 pipes per 1,000 pipes. According to these figures therefore there is a probability that after the second year the renewals per economiser will be about one pipe every five years. These averages, based on the above-mentioned 17 official reports, are in excess of the renewals amongst our members. Our more favorable experience is no doubt due to the fact that a very careful record is kept of the pipe gaugings by our inspectors, and when certain limits of wasting are reached we advise renewals to prevent inconveniences. Thus in the Brighouse explosion it appears that our inspector's reports about the extent of the wastings were in the closest agreement with the measurements made on the broken pipes, viz., 3-16 in. Unfortunately, however, at least for those who attach extreme importance to average results, it was not the most wasted pipes, which had all been located in the A block, but some pipes in the B block which gave way, evidently by drawing out of their sockets. This block was a comparatively new one, and being in the second group these pipes were but slightly wasted.

The makers of the economisers are very positive that, at present, at least, failures of cast-iron pipes are far less frequent than the above estimate from the official reports, but they admit that there are a fair number of renewals every year. Violent explosions occur on an average only once in four years. The ratio is possibly one or perhaps two thousand pipe renewals to one serious explosions.

The explanation of this discrepancy is that under ordinary working conditions, economisers are full of water, which is cold at the bottom ends of the pipes and hot at the top. If a pipe fails at the bottom end, as is usual, cold water runs out, and as appears from reports Nos. 485, 1,590, 1,856, 1,970, the first intimation about anythisg being wrong is that the water-level in the boiler is noticed to be sinking, or water is seen to be running out of the flue. However, if, as in the Brighouse explosion, and in cases Nos. 220, 242, 1,790, a pipe fails in an economiser through which hot flue gases had been passing for some time, while the feed supply was shut off, it is evident that the whole mass of the water in the economiser will have been raised to the temperature of the water in the boiler, and as hot water under pressure can be looked upon as containing about 30 times its volume of steam, it is evident that if under these circumstances it is the turn of one pipe of an economiser to burst, a very large volume of high-pressure steam is suddenly liberated and a destructive explosion is the result.

If the feed supply be suddenly shut off while the flue gases continue to pass through the economiser, it takes about half an hour before the water temperature is sufficiently high to generate steam, which then either escapes into the boiler or, if the feed valve has been closed, it escapes through the safety valve. Now if we assume that there have been 1,000 harmless failures during a period of four years, equal to 60,000 half hours of working time, then if we knew the number of economisers at work, certainly several thousands, and if we knew how often a fireman negligently shuts off the feed and yet allows the hot gases to pass through the flues, we could estimate the chances of the two things happening together, and a destructive explosion occurring. Conversely as we know that this coincidence takes place about once in 60,000 half-hours, we might estimate the frequency of negligence on the part of the firemen in terms of the number of economisers at work. Adopting some reasonable number it will be found that, on an average, one or other of the firemen somewhere in the United Kingdom is alway behaving negligently. This conclusion is somewhat startling, but on reflection it is not an improbable one. Many a fireman does not know that he ought to close the damper when he temporarily shuts off the feed, because he has never been told, and amongst those who have been told to shut their dampers, there are many who, having on one occasion accidentally omitted to carry out their instructions and found that no harm resulted therefrom, will have been less careful in the future than they were in the past.

Nevertheless, Report No. 2,470, on the Brighouse economiser explosion, just issued, lays it down that the explosion was caused by a damper being accidentally left open. The wording is:

"The cause of the explosion was the omission to close the dampers of the economiser flue of the high-pressure section of the economiser when that section was intended to be put out of use, and the feed valve inlet and outlets had been closed for that purpose. The result was that the high-pressure section of the economiser became a closed vessel in which steam generated to a pressure which it could not withstand, and in consequence exploded."

The above remark implies that the economiser was not a closed vessel until somebody closed the feed valves, and the natural tendency is to blame the person who shut the feed valves. But that is quite a wrong view of the case. The economiser was a closed vessel, otherwise the enquiry could not have been held, for the Boiler Explosions Act, 1882, defines a boiler as being a

SUMMARY OF BOARD OF TRADE REPORTS ON ECONOMISER EXPLOSIONS.

Report No.	Dates of I. Build. II. Explosion	Age. Years.	Number of Pipes	Renewal of Pipes	Economiser Pressure. Lbs.	Thinnest Metal of Pipes. Inches	Maximum Stress. Tons.	Nature of Explosion.	REMARKS. (Bracketed information by M.S.U.A. Inspectors.)
106	? 2/1/1885	9	6×24 =144	No renewals.	120	5/16 average.	—	Destructive	All economiser valves were closed and safety valve exhaust probably frozen. A case of overpressure.
154	-/-/1877 13/11/1885	8	8×16 =128	3 in '78	235	1/8 (1/4)	1·68	Destructive	Report silent on question of feed working (only one pump available) and of dampers being open.
186	-/-/1867 25/6/1886	19 and 10	8×24 =192	No renewals.	180	1/16 (1/8)	2·54 (0·66)	Semi-destructive. Two rows and two pipes.	Explosion at 7-10 a.m. Dampers open all night. (Two pipes drawn out of sockets.)
220	-/8/1882 7/5/1887	5	6×16 =96	2 in '86 1 in '87	131	1/8	0·94	Destructive. Sharp report.	(Feed and delivery valves closed since morning.) Dampers not closed till some hours before explosion.
242	-/6/1875 22/8/1887	12	8×52 =416	3 in '84 5 in '85 2 in '86 3 in '87	142?	Not reported. (under 1/8).		Destructive. Hissing noise before explosion. Some pipes discoloured by heat.	Explosion 15 minutes after starting engine. Economiser doors had been open all night and feed supply stopped. Graphitic corrosion.*
485	-/-/1860 2/4/1891	31	6×8 =48	9 about '85	154	1/16	2·16	No report heard. Water level in boiler sinking.	A case of wear and tear.
566	1873, 1881 23/3/1892	19 and 11	6×32 =192	12 in '89	212	1/8	1·51	Destructive. Pipes hurled upwards.	Overheating suggestion was rejected but was probably correct.
647	-/-/1885 27/5/1892	7	8×28 =224	1 in '87	120?	1/4	?	Destructive	(Economiser valves closed). Safety valve blanked off. (Flue dampers bad fit).
1590	-/-/1877 30/8/1905	28	6×20 =120	No renewals.	120	Not reported.	—	No report heard. Water ran out of flue.	A case of wear and tear.
1687	-/-/1902 15/5/1907	5	6×24 =144	12 loose in '02, 14 in '06	112	1/32 to 3/32		Destructive. Report says Gas explosion.	Explosion occurred while cleaning fires, and while water level was high. Feed probably shut off. Hydraulic test 11/12/06 to 240 burst a pipe 1/8in. thick; stress, 1·78 tons.
1790	1903, 1905 7/9/1908	5 3	8×16 =128	No renewals.	257 then 299	5/8	2·13	Destructive. Pipes drawn out of sockets.	The feed was shut off while hot gases passed through economiser. (The photograph, Plate II., shows a pipe broken in socket).
1856	-/-/1901 6/5/1909	8	8×20 =160	3 in '08	190	3/8 but cracked.	—	Light explosion. One old crack revealed.	The hydraulic test of one month previous did not show up old crack, or else it started it.
1970	-/-/1904 27/6/1910	6	8×12 =96	2 in '09	165	Not reported.	—	No report heard. Water ran out of flue.	A case of wear and tear.
2080	10/1890 11/1901 2/8/1911	21 10	8×24 =192	No renewals.	120	1/16	1·69	One dull, one sharp report. Only the old economiser destroyed.	Curious case if correctly reported. 1910 hydraulic test to 190lbs.; stress, 2·68 tons. No failures.
2251	-/-/1911 30/1/1913	1	12×36 =432	No renewals.	166	1/2	0·315	Three top boxes burst longitudinally. Also 15 transverse fractures. Two pipe fractures in sockets.	The cause was doubtless weakness of boxes, or excessive forcing in pressure.
2257	— 18/6/1913	6	6×12 =72	No renewals.	155	1/8	1·11	Only one tube shattered.	Curious case. Shattered tube suggests that there was steam in the economiser. Report silent on this point.
2470	-/7/1909 6/11/1918	9	10×24 =240	1 in '17 3 in '18	198	— (5/16)	— (0·96)	Destructive	Reported cause: accidental omission to close damper. Real cause: a number of circumferential cracks in sockets.

*Note for Table II., Case 242. ANALYSIS OF ORIGINAL PIPE AND GRAPHITIC CORROSION.

	Cast-iron pipe M.S.U.A. per cent.	Graphitic Corrosion M.S.U.A. per cent.	Graphitic Corrosion B.T. per cent.
Silicon	2·08	—	—
Sand	—	22·22	3·20

Black Oxide	—	72·79	84·60

The Board of Trade Graphitic Corrosion was probably obtained from another cast-iron vessel. According to our (M.S.U.A.) analysis 48in. per cent. iron has been dissolved out.

TABLE 2.

closed vessel. Thus although the Commissioners might plead that they were merely quoting the words of the Act, they do so in such a way as to make it appear that some person had changed the economiser from being an open vessel into becoming a closed one.

It is not intended to indulge in speculations as to why the Commissioners adopted this course; why, in the abovementioned sentence, they did not state that this so-called vessel was provided with a safety valve of ample size, which was doing its duty by blowing off steam, nor why the Commissioners disregarded the evidence of the Board of Trade Surveyors, and all other engineers, and entirely omitted from their report any mention of the real cause of the explosion. However, in view of the importance of this case, it has been thought desirable to go into some detail on several of the points which do not appear in the report, though they were given in evidence, or which are dealt with in an unsatisfactory manner. No details are given in the report of the reduced thickness of the pipes, though 3-16 in. was mentioned in the evidence. Assuming a tenacity of 2.35 tons per square inch (see experiments p. 23), the bursting pressure would be 490 lbs. per square inch, but if, as may be, the tenacity was twice as great, the bursting pressure would be about 1,000 lbs. The pressure to which the safety valve was loaded, was 188 lbs., and it is ridiculous to imagine that the valve, which was quite free in action, should allow an accumulation of over 400 per cent. of pressure. In fact, there would not be enough heat in the flue gases to produce any accumulation.

Economisers collect about 15 per cent. of the heat supplied to their boilers. In this case the boilers had 88 sq. ft. of grate area, and at 188 lbs. would, according to the Board of Trade rules, require a safety valve area of 16 sq. ins. Therefore 15 per cent. or 2-4 sq. ins. would have sufficed for the economiser.

The safety valve was 1 15-16 in. diam., or 3 sq. ins. area and, therefore, amply large enough to relieve the economiser of any excess of pressure. For a pressure of 490 lbs. a safety valve of 1 1-8 in. diam. would have sufficed, and for double that pressure a safety valve of 7-8 in. diam. would have been sufficient. There is, therefore, absolutely no justification for the Commissioners' suggestion that an excessive pressure was generated in the economiser.

During this very prolonged enquiry, at which I was present, occasional questions were asked about the effect of passing hot gases through an economiser while out of use. It is, therefore, desirable to deal with this point. The temperature of flue gases is about 600 degs. Fah., or about equal to that of superheated steam. Now superheated steam can safely be passed through cast-iron pipes and into cast-iron cylinders of engines which are subjected to innumerable reversals of stress, without any failure occurring. Then again during the early days of electric power stations, when the peak load demand was often far in excess of the boiler power, it was quite a common practice to shut off the feed during the peak load period while allowing the flue gases to continue to pass through the economisers, thus converting them temporarily into steam producers, and thereby raising the boiler power by about 30 per cent. The chief engineer of one of the largest power stations of those days has recently confirmed what he told me years ago, that he knew at the time that he was producing steam in his economisers. He had no failures during these periods (evidently it was not the chance turn of any of his pipes to rail during the hour of maximum peak load) and now that they are 10 or 12 years older than then, they are still working satisfactorily. Then again, it is well known that the makers of economisers at one time thought that water-tube boilers could be made of cast iron, and they actually worked an economiser as a steam generator. They had troubles and gave up the idea, but they had no failures. That they at least have no fear of failure in case the feed should be shut off, and dampers left open, is evident from the fact that in their working instructions to firemen there is not a word to suggest that dampers should be shut whenever the feed is shut off or that the economiser would explode if this were not done. In fact if the leaving open of a damper were known to lead to an explosion, anybody who advises the use of a vessel which would explode every time that a careless fireman forgets to shut a damper is a criminal.

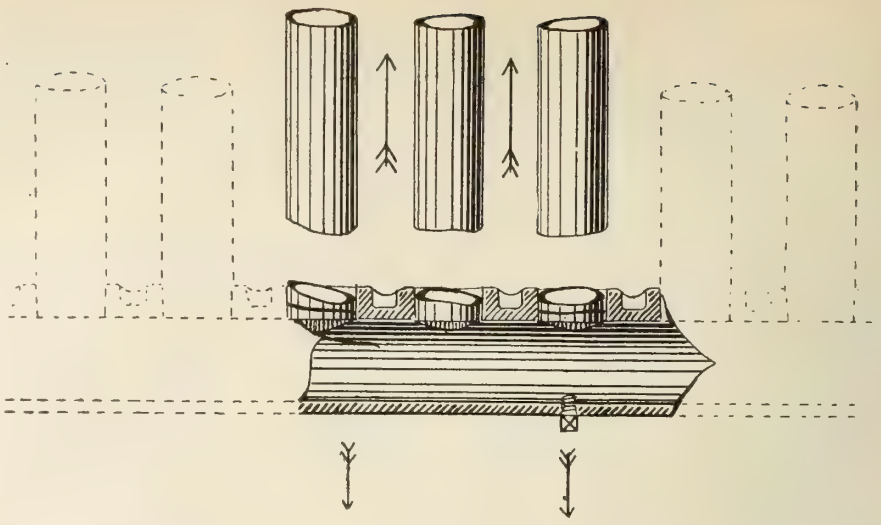
Had the report contained this conclusion, and its corollary—that all existing economisers must be scrapped—engineers and steam users would have dismissed the report with a smile; but the seriousness of the present report (No. 2470), and the reason why it has been specially mentioned here, lies in the fact that it omits to mention certain old fractures. Two "competent and independent engineers, practically conversant with the manufacture and working of boilers," were selected by the Board of Trade from among their own staff to make the preliminary enquiry, and had carried out their task with the most painstaking care. These and other engineers refused in their evidence to admit that the open damper could have caused the failure of any of the pipes, and attributed the explosion to the just-mentioned old fractures. By withholding this information the report deprives the engineering profession of the means of studying the problem of economiser safety, and were thus hampering them in their constant efforts to make structures safer and safer. This course may have seemed to them a natural one, for the cart had been put before the horse in this enquiry, and instead of first ascertaining the nature of the explosion and its cause, and who was responsible for this, the first three or four days were devoted almost exclusively to subjects of personal responsibility which had already been disposed of in so many hours at the coroner's inquest. Sworn evidence was taken as to when and how the victim was killed—whether the works manager, his engineer, or the leading stoker, or the company, was responsible for his death, or for appointing the man who may have caused his death. This wearying evidence, which lasted for several days, was absolutely valueless, except for the purpose of confirming or reversing the verdict given at the inquest. But the commissioners have no power in this respect; their power is limited by the Act to adding to the evidence—which, as in this case, is filed away in the Board of Trade archives—"any observations on the evidence or on any matter arising out of the investigation." The report, but apparently not the evidence, nor, it would seem, the remarks which the commissioners may feel inclined to make on the evidence, must be published by the Board of Trade.

The intention of the Act was that the publication of reports on the causes of explosions should enlighten engineers and steam users, and thus pave the way for reducing the risk of explosions, and the present report, therefore, ought to have contained not merely the observations of the commissioners on the evidence, but, above all things, a statement as to the cause of the explosion. It should not have fastened on one of several coincidences and misinterpreted the words "closed vessel." Unfortunately, in legal circles great confusion seems to prevail with regard to the meaning of the words "cause" and "coincidence." This is, of course, excusable, for it has been a human failing through all ages to attach importance to coincidences, even to the positions of stars at the birth of children. Engineers, however, may be pardoned for not wishing to be guided by coincidences. They will refuse, and rightly refuse, to admit that because once every fours years the opening of a damper coincides with one of the thousand of economiser pipe failures, therefore economiser explosions are caused by leaving dampers open.

Having discovered the cause of the explosion, but which engineers would merely call a coincidence, it was, of course, quite natural that the commissioners should attach no value to expert evidence on subjects which they considered of no importance, and should refuse to listen to evidence about experiments made specially for the enquiry, and should, as already stated, banish from their report all mention of some very important evidence about old circumferential fractures in the pipes, to which their predecessors in this enquiry attributed the explosion, the broken pipes being actually shown to the commissioners.

Reports Nos. 186, 566, and 1,790, and particularly the illustration in this last report, suggest very strongly that in these economisers, too, some of the pipes were fractured circumferentially, but in the absence in these reports, of any indications as to whether they include all the essential facts, it is impossible to say whether these fractures existed and were discovered, and if so whether mention of them was kept out of these reports or not.

A part of one of the bottom boxes of the present economiser is illustrated in Fig. 1, which represents a section through the broken piece, now in our museum. The dotted lines indicate the continuations of the box, which could not



be found, and the arrows are intended to show how the box and the pipes moved relatively to each other when they parted company and caused the explosion. This box had been removed from the site of the explosion, and it is, therefore, impossible to say definitely whether it belonged to the old worn-out A block or to the comparatively new second block B. Judging, however, by the upper fracture of the left-hand pipe (Fig. 1), which includes the waist of the wasted portion of this pipe, where it is ⅝ in thick, this box belonged to the B group. It also appears that the flue arch which fell in, was situated under the B block. This failure will have been caused by a bottom box of that group becoming detached and striking the top of the flue. An examination of Fig. 1 shows that two of the remaining three pipes had two circumferential cracks in the sockets. Of these the lower ones were quite old, and the upper ones seemed to be older than the explosion.

In consequence of this discovery special attention was paid to the ends of the pipes of economiser parts which have had to be rejected when new, after the first hydraulic test. Even at this early stage of their lives occasional pipes were found to be cracked circumferentially in their sockets. These facts, the knowledge that there are zones of severe shearing stresses near to the nipped portions of the pipes, and the knowledge that cast iron has no great shearing strength, may be a guide to researchers into this interesting subject.

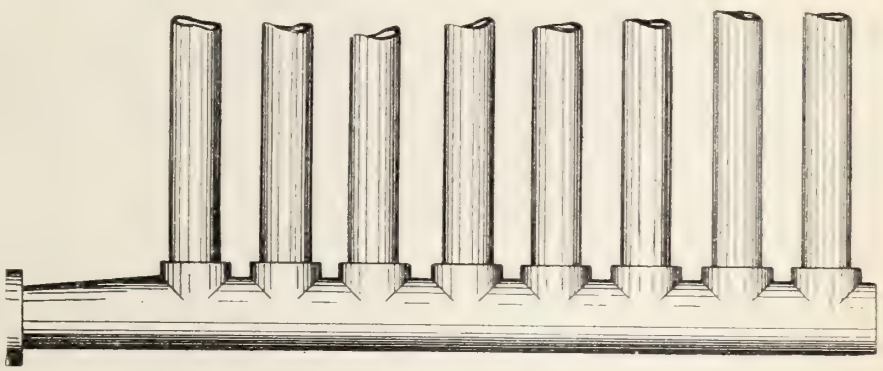
In order to test this point a model economiser was made of glass pipes, which, according to Table IIa, should break under a side pressure of 14 pounds per square inch. The central tubes were replaced by an air reservoir whose end was closed with a celluloid disc. This disc burst with a loud report, as of a pistol shot, when the pressure had reached about 300 pounds, but no pipes were broken. On repeating the experiment, with broken pipe ends piled up over the celluloid, some of the vertical pipes were broken. It is intended to repeat this experiment at the M.S.U.A. annual meeting, for it shows that side-pressure alone, without flying fragments, will not fracture pipes. This simple experiment definitely settles the vexed question about the flue-gas explosions. These cannot burst economiser pipes. It also explains that it is a mere matter of chance whether a pipe explosion will confine itself to one pipe or sheet as in cases Nos. 186, 1,856, and 2,257, or whether it will be a destructive one, as in cases Nos. 154, 220, 566, 647, 1,790, 2,080. In the one set of cases the flying fragments of the first pipe, or sheet, which burst, evidently did not strike the adjoining pipes, and the liberated pressure alone could not break them; in the other set the surrounding pipes were evidently struck by fragments.

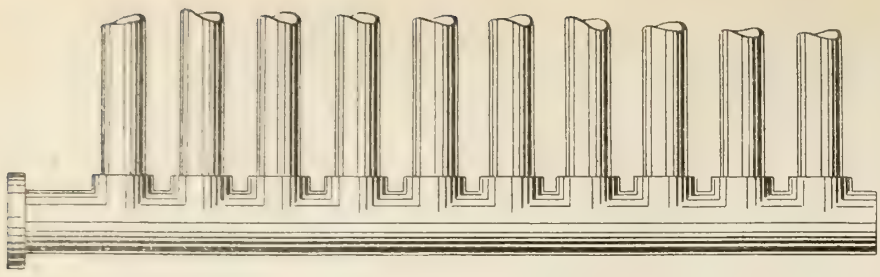
Destructive economiser explosions like the present one are extremely rare and difficult to understand, and it is, therefore, very regrettable that the enquiry was not carried out in harmony with the spirit of the Boiler Explosions Act, which says that the commissioners shall report on the cause of the explosion. As already explained, the commissioners' view of the cause of this explosion is obviously a wrong one, but whether it be right or wrong it ought to be correct in its details. Thus, they assert that the explosion was caused by the leaving open of a damper and closing the valves, but they make the wrong assertion that the economiser was now a closed vessel, omitting to mention that it was provided with a safety-valve of ample size. If this very important fact had been mentioned their assertion that the economizer exploded owing to over-pressure (of which there was absolutely no evidence) could hardly have been made, and then they would have had to explain how their alleged cause acted. Did it result in overheating and if so, does overheating weaken iron? (Experiments show that up to a fairly high temperature the tenacity does not diminish.) Does this overheating slacken the tubes in their sockets? (There was no indication of this amongst the fragments.) The fact is that the commissioners, of whom one or more has to be "a competent and practical engineer specially conversant with the manufacture and working of steam boilers," do not actually make their investigations in such a manner as "to enable them to make the report hereinafter mentioned, which report shall be a full one on the cause of the explosion." The investigation is, in effect, carried out by the solicitor of the Board of Trade, who brings forward sworn evidence, though the swearing is not required by the Act, and without any warning to the witnesses, these may now be cross-examined both by their own side and by the commissioner, and then very often their own sworn evidence is used against them. This is un-English and not as it should be.

It is unfair to witnesses who wish to give the commissioners every assistance, and as the whole atmosphere is now a legal one, even a Lord Advocate once appearing for an insurance company, the technical causes of exeplosions are hardly inquired into.

Now, in this almost unique case, if one or more engineers having a free hand in the matter could have enquired into those economiser points which have always been a mystery, they would certainly have investigated the strength and quality of the cast iron, its behaviour when heated, on the holding power of the sockets, and above all, on the causes of the circumferential fractures, more particularly why they seem to have been confined to one bottom box. If such engineering commissioners had thrown any light on any of these points, their report would have been highly valued by engineers, but the reports produced under the present system are not of this class, and few engineers pay any attention to them, so much so that when the influential British Engineering Designs and Construction Committee, which recently issued Standard Conditions for the Design and Construction of Marine Boilers, were deliberating on this subject, the Board of Trade reports were apparently not consulted even though their chief engineer attended the meetings.

Yet these reports could be made valuable if the system which our Explosions Act was intended to perpetuate, were carried out. Before, and even after, 1882 this association made it its duty to investigate boiler explosions. But we did not send our surveyors in rotation to do this work, as is the Board of Trade practice. We confined these enquiries to one assistant who soon grew to be an expert enquirer into explosions, as is proved by the very valuable reports furnished by him and formerly published by us. I have on several occasions suggested that instead of appointing every one of their surveyors in rotation to investigate explosions, the Board of Trade should retain an "independent engineer, practically conversant with the manufacture and working of boilers," as required by the Act, and instruct him to make thorough enquiries whenever an explosion occurs, both into the design of the boiler, the strength of its material, and the conditions of working. The Board of Trade surveyors would be relieved of suddenly-imposed tasks which interfere with their routine duties, whereas many an independent engineer thoroughly qualified both theoretically and practically to discover the causes of explosions would enter with enthusiams into the investigation of interesting engineering problems. The heavy legal expenses of the present formal enquiries, which would then rarely be necessary, would be set off against such an independent engineer's fees and expenses, including experiments. Judging by conversations which I have had with Board of Trade





surveyors, and also with chiefs of boiler insurance companies, the retaining of an independent engineer for explosion enquiries would be most welcome and sure to add to our knowledge of the safe working conditions of boilers.

There is one point with regard to the safety of economisers which deserves a closer study. This is the question of deterioration of the cast iron. It will be remembered that in my Memorandum for 1916-17, dealing with enquiries into boiler shell explosions, I found that wrought iron which has been wasted down to about ⅛ in. or 1-16 in., has lost its nature and should not be credited with any tenacity. Does cast iron behave in the same way? Two tests were carried out on this subject some years ago.

First Test

The sheet of eight pipes gave way at the bottom end of one of the pipes (see Fig. 2), at a pressure of 620 pounds per square inch, a triangular piece, 6¼ in. × 2¾ in., being blown clean out. The thickness of this piece varied from ¼ in. to 9-32 in. The internal diameter of the pipe was 4 in., and the mean diameter 4¼ in. The tenacity of the cast iron was therefore

$$\frac{4\frac{1}{4}\text{ in.} \times 620\text{ lbs.}}{2\text{-}4\text{ in.} \times 2{,}240\text{ lbs.}} = 2.35\text{ tons per sq. in.}$$

Second Test

The sheet of ten pipes gave way at the bottom end of one of the pipes (see Fig. 3), at a pressure of 350 pounds per square inch, a piece about 9 in.×2 in. being blown out. The thickness of this piece varied from 1-16 in. to ⅛ in. The internal diameter was 4 in., and the mean diameter 4 1-16 in. The tenacity of the material was therefore

$$\frac{4\text{ 1-16 in.} \times 350\text{ lbs}}{2\text{-}16\text{ in.} \times 2{,}240\text{ lbs.}} = 5.08\text{ tons per sq. in.}$$

See also Table II., Report No. 1,687. Bursting stress 1.78 tons.

The lowness of these tenacities is probably due to the deterioration of the material in its exposed position and is, of course, taken into account by us when reporting on the fitness of our members'

HAVANA CENTRAL STATION TO DOUBLE POWER-PLANT CAPACITY

On account of a rapid growth of load and the possibility of a still further growth in the next few years, the Havana (Cuba) Electric Railway Light and Power Company has just ordered two 25,000 kw. Westinghouse steam turbine-generators to double the plant rating. At present there are, in this plant, three 12,500 kw. generators supplying a combined railway and power load. In the original installation, space had been provided for only one additional unit, but now that the load has become so great it was thought necessary to increase the capacity still more. Consequently the two 25,000 kw. units were ordered, one to be installed in the space available, and the other to replace one of the 12,500 kw. units. By this means it is unnecessary to extend the power plant buildings. However, the 12,500 kw. unit is in perfect operating condition and will probably be utilized elsewhere.

The first unit will be installed and will be in operation in 1921 and the second one will be on the line in 1922. The units are to be designed to operate at 185 lbs. pressure, 150 deg. superheat and 28 in. vacuum. In addition, arrangements have been made to operate this equipment at higher pressure and superheats if desired at a later time.

To go with these turbine-generators, Westinghouse Le Blanc 56,000 sq. ft. surface condensers and Le Blanc air and circulating water pumps have also been ordered. Each condenser will have two circulating pumps and divided water boxes so that one-half of the condenser may be cleaned while the other half is in operation.

This station, which is the largest in Cuba, is modern in every respect and has an operating economy which is comparable with some of the best plants in the United States.

The average fuel consumption is less than 2 lbs. of coal per kw. hr. notwithstanding that the plant has a low load factor. This economy is due to the excellent operation and maintenance afforded by the management and operating engineers of the plant.

COAL CONSERVATION FILM AVAILABLE FOR EXHIBITION

Engineering clubs and societies, manufacturers' associations, commercial organizations, technical schools, and the educational departments of large corporations will be interested in the announcement that the Diamond Specialty Co., Windsor, Ontario, now has available for free distribution three copies of its motion picture, "Coal is King." This picture was prepared from a scenario by Robert June, and the pictures were taken under his direction by the Ford Motor Company.

The film was originally prepared as part of the Coal Conservation Campaign used during the war, but has just been completely revised and brought up to date, all war material being eliminated and much new material added. The film deals with good and bad methods of coal mining and transportation, good and bad methods of firing, combustion losses and their minimization, power plant instruments such as draft gauges, CO_2 recorders and their uses, losses caused by leaky boiler settings, good and bad management of the boiler room, and the necessity for keeping the boiler surfaces clean is properly brought out. Pictures of scale and soot removal, losses caused by firing the boiler too high or too low above or below rating, losses caused by cutting in stand-by boilers too early or too late, losses caused by uncovered steam pipes, leaky pipes, steam traps, etc., are shown.

The film is in four reels, requiring approximately 50 minutes to be shown. Bookings are now being made for the summer and fall, and those interested should make their reservations without delay in order that schedules may be completed.

MINIATURE CATALOGUE DESCRIBES WATTHOUR METERS

The Westinghouse Electric Manufacturing Company, has issued miniature catalogue 3-A-1, measuring 4 in., by 7 in., which describes and illustrates its lines of watthour meters. In this booklet the following instruments are described as to the operation, distinctive features, construction and application: Type OA watthour meters for alternating current service, type OA prepayment watthour meters, type RO watthour demand meters, (single phase and polyphase); type RA recording-demand watthour meters (polyphase), type RH thermal demand meters, type CW-6 watthour meters, and portable standard watthour meters.

The information contained in this catalogue is the same as that on pages 625-638 inclusive of the Westinghouse annual supply catalogue and descriptive leaflet No. 3484.

A Swedish engineer, remarks "Engineer," ran several incandescent lamps at temperatures of 200 degrees Cent., while others cooled by water were worked at about 2 degrees Cent. After some hour's running in the case of the lamps at a temperature of 200 degrees the luminous intensity had dropped considerably, and they were unusable after forty hours' running, whereas with the lamps run at 2 degrees the diminution of intensity was inappreciable after that period. This deterioration is apparently explained by the fact that at high temperatures the glass of the bulb becomes porous and air enters the bulb, and it also explains why, where large numbers of lamps are arranged close together in advertisement signs, etc., they rapidly deteriorate.

A Course of Instruction for the Graded Certificate

We Will in This Course Go Through the Mathematical and Theoretical Work to Cover Every Grade of Certificate Issued by the Ontario Board

By T. H. FENNER

WE have covered the ground fairly well in the two previous lessons as far as fractions and decimals are concerned. By this we mean that we have given sufficient indication of the methods of using these functions to enable the student to perfect himself after a little practice. We propose now to indicate the methods of raising numbers to their different powers, and of extracting the roots of the various powers of numbers. These operations are known as involution and evolution. While it is as well to know how to perform these operations arithmetically, we would like to emphasize here that it is far more easy to use tables, either those giving the powers and roots of numbers, or logarithmic tables. It is not only easier, but there is less liability to error, while time is saved which would be used in making long calculations. There are cases where the only way to get the result is to use either tables or logarithms. However, we will indicate the method of getting the square and cube root by the ordinary arithmetical way, and leave it to the reader to find out the use of the tables, or logarithms if he feels like it. We may take up the use of logarithms at a later stage of these articles, but at present we wish to get over the preliminary ground as quickly as possible, and reach the actual engineering problems.

Involution

Involution is the act of multiplying a number by itself a given number of times, the number itself being the root, and the times it is multiplied by itself being the power of the number. The power to which the number is to be raised is indicated by a small number placed above and to the right of it, as for instance 3^2 which signifies that 3 is to me multiplied by itself once, or in other words, to be raised to the second power, or as usually expresesd, to be squared. If it is 3^3, it means 3 is to be multiplied by itself twice as $3 \times 3 \times 3$ or to be raised to the third power. The same applies to all the powers, as 3^4, 3^5, 3^6, and so on. The small number is known as the index or exponent of the power.

In multiplying together two powers of the same number as $3^2 \times 3^3$, the exponents or indices are added together, thus $3^2 \times 3^3 = 3^5$. Two powers of the same number are divided by subtracting the exponents thus: $3^4 \div 3^2 = 3^2$. If we have $3^2 \div 3^4$, we get as the result of the subtraction, $2 - 4 = -2$, then the exponent will be 3^{-2} or three to the minus 2 power. Now the minus 2 power can be expressed by making the number the denominator of a fraction with one for its numerator, and raising the denominator to the power indicated. Thus 3^{-2} would be written as $1/3^2$. Take $2^5 \div 2^9 = 2^{-6} = 1/2^6$: The exponent of the power may be a fraction and then means that the number is to be raised to the power shewn in the numerator, and the root as expressed by the denominator extracted. For instance, take $2^{2/3}$ means that the cube root of 2 squared is to be taken, or we might write it as $\sqrt[3]{2^2}$. If written thus, $2^{1/2}$ we know it means to take the square root of 2, because the first power, as expressed in the numerator of the index, is the number itself. 2 to the first power is 2. The zero power of a number always equals 1. Thus $2^0 = 1$, $3^0 = 1$, $3^1 = 3$, $3\frac{3}{3} = 3$. There is no limit to which a power can be raised, but in practice it is only the first two or three powers which are in general use.

For the work we are concerned with the square, cube, and fourth powers and roots will be ample.

Evolution

The extraction of the root of a power of a number is known as evolution. In the ordinary way, it involves a lot of work, and is better achieved by the use of tables. However, in order that it may be of use in refreshing the memory of some, and instructing others, we will give herewith the method of extracting square root and cube root by the arithmetical process. Square root is comparatively simple, but cube root is more involved. The fourth root can be obtained by extracting the square root, and then extracting the square root of the result. In other words, it is the square root of the square root. The sixth root is the square root of the cube root. The ninth root is the cube root of the cube root. If a number is to be raised to a power, and a different root extracted, the whole thing can sometimes be done by dividing the index of the root into the index of the power. Thus $2^{6/3} = 2^2 = 4$. $2^{3/3} = 2^1 = 8$ and so on. The small figures in this case representing fractions.

The method of extracting square root will now be explained in detail. The first thing to be done is to space off from the unit figure every two figures. If we have a number 784, which we want to extract the square root of we will start at the figure 4 and space off to the left. We will have 784

Now take the first figure 7 and divide it by the greatest number whose square is less than 7. The square of 3 is 9, so that is too much. The square of 2 is 4, so we can take that. This will be the first figure of the quotient and the sum is set down as follows:

```
784(2
4
-
3
```

The next operation is to bring down the two figures remaining, and place them after the 3, making the sum.

```
784(2
4
—
384
```

We then multiply the first figure of the quotient by 2, and bring the product down to form the next trial divisor. We now have

```
      784(2
      4
      —
4     384
```

4 is now the first figure of a new divisor for the number 384. We try 4 into 38. It will go 9 times. We place 9 after the 4 and try it, thus $49 \times 9 = 441$. We see it is too much. We then try 8, which makes $48 \times 8 = 384$. We see this is an exact dividend. We therefore place 8 in the quotient and alongside the 4 and we now have:

```
      784(28
      4
      —
48    384
      384
      —
      ...
```

And the square root of 784 is 28. Let us take another number, say 4225. Proceed as at first, spacing off each second figure from right to left. Then we have 42.25.

What is the greatest number whose square is less than 42. We can decide this mentally. It is 6, so we have

```
42.25(6
36
—
.6
```

and bringing down the next two figures

```
4225(6
36
——
.625
```

We then multiply the first figure of the quotient by 2, as before and get 12 as the first part of the trial divisor, which gives us:

```
      4225(65
      36
      —
125   .625
       625
       —
      ...
```

65 being the required square root.

In both the preceding cases, the root has come out even, but this is not always so We may have a fractional result, and it is usual to make this a decimal, as it is very simple to carry out. Let us find the square root of 8. The nearest root figure we can think of is 2, the next 3 being too large, and the square of 2 is 4, thus giving us the following:

```
8(2
4
-
 4
```

There are no more figures to be brought down, and we have a remainder of 4. We proceed as follows: Put a decimal point after the 2 in the quotient, and add two ciphers to the remainder in the dividend. Thus we will have :

```
8(2.
4
---
4   400
```

We have then 4 as the first figure of our trial divisor. What will be the second 4 into 40 will go 10 times, but that is not practicable. Try 9 which would make the divisor 49, and the next figure of the quotient 9. $49 \times 9 = 441$ which we see is too much. Let us try 8 which gives $48 \times 8 = 384$ which will go. We now have:

```
8(2.8
4
-
48  400
    384
    ---
    .16
```

We must now bring down two more ciphers, and multiply the quotient by two for a trial divisor, thus:

```
8(2.8
4
-
48  400
    384
    ---
56  .1600
```

The next figure will be 2, by trial, and we can proceed. Each new trial divisor is found by doubling the root all ready determined, and the dividend is continually renewed by adding two ciphers. The root is carried to as many places of decimals as is thought necessary, though of course, it might never work out exactly. Let us see how far it goes:

```
8(2.828427
4
-
 48  400
     384
     ---
 562 .1600
     1124
     ----
 5648 47600
      45184
      -----
 56564 .241600
       226256
       ------
 565682 .1534400
        1131364
        -------
 56568547 .40303600
```

We can dispense with any further decimals and call the square root of 8 — 2.8284. Suppose now, we have to find the square root of a decimal fraction and a whole number, we proceed just the same. The figures before the decimal point are spaced off in twos from right to left, and those after the decimal point from left to right. The root is then extracted in just the same way as before.

Find the square root of 25.25:

```
25.25(5
  25
  --
   25
```

Here, we have found the complete root of the integral part of the number, and now have the decimal part remaining. Multiply the root already found for the trial divisor, and place a decimal point after the first figure of the root. We then have the sum in the following form:

```
25.25(5.
  25
  --
10   .25
```

As we cannot divide 10 into 25 and still provide for the second figure of the root, we add a cipher to the quotient and one to the trial divisor, and add two ciphers to the dividend, giving us:

```
25.25(5.0
  25
  --
100  .. 2500
```

We can now divide, 2 being the figure to add to the root, and then proceed as usual:

```
25.25(5.02493
  25
  --
1002  2500
      2004
      ----
10044  49600
       40176
       -----
100489 .942400
       904401
       ------
1004983 .3799900
```

The square root to 5 places of decimals is 5.02493 which is not an exact result, but is very slightly in error, as a simple proof will show.

```
   5.02493
   5.02493
  --------
   1507479
  4522437
 2009972
1004986
2512465
--------
25.2499218049
```

Leaving off all decimals after the fourth the error is $25.25 - 25.2499 = .0001$ or $\frac{1}{10000}$. The square root of a decimal quantity is found in the same way. The square root of .5 will be found in this way.

As there is only one figure after the decimal point, we add a cipher and make it .50. The nearest square root is .7 and we have:

```
50(7
49
--
14   .100
```

We must add a cipher in the quotient and one in the divisor, adding two to the dividend, thus getting:

```
50(7071
49
--
140   10000
1407   9849
----  -----
14141 ..15100
        14141
        -----
        ..959
```

the root is then .7071.

If we had to find the root of .05, we would be able to go straight ahead, as we would then have two figures after the decimal point. The reason there must be two figures after the decimal point is obvious after a little thought. When we multiply decimals, the product will have as many places of decimals as there are in multiplicand and multiplier. Therefore in the case of .5, the square root cannot be .2 as .2 multiplied by itself gives .04. On the other hand, the square root of .05 is .2236. The square root of .005 would again be different. Pointing off, the first two figures would be ciphers. We would, therefore, put a cipher in the quotient after the decimal point and bring down the next two figures. There is only one, 5, so we add a cipher to that, and then take the nearest root. The work is as shown:

```
.005(.0707
00
--
  50
  49
  --
1407 .10000
       9849
     -----
14    ..151
```

This should be sufficiently clear to all by now.

In taking the square root of a fraction, the square root of denominator and numerator are taken separately. For instance, the square root of $\frac{25}{36}$ would be $\frac{5}{6}$. When a fraction is to be raised to a power, it is indicated by enclosing it in a bracket and putting the exponent or index at the top right-hand corner, as:

$$\left(\frac{5}{6}\right)^2 \text{ or } \left(\frac{3}{6}\right)^3, \text{ etc.}$$

When the root is to be extracted, it is written $\sqrt[5]{\frac{}{6}}$ or $\sqrt[3]{\frac{}{6}}$ as the case may be. Find the fourth root of $\frac{625}{1296}$ would be written $\sqrt[4]{\frac{625}{1296}}$. First find the square root of $\frac{625}{1296} = \frac{25}{36}$. Then take the square root of the latter $\sqrt[2]{\frac{25}{36}} = \frac{5}{6}$.

We could give examples indefinitely, but feel that the foregoing should serve all practical purposes.

A Series of Articles on Power Plant Management

This Article Deals with Boiler Feed Water Heaters, the Merits of the Open and Closed Types Being Compared.

By ROBERT JUNE

Feed Water Heaters

WHAT does a feed water heater accomplish? If I have not a feed water heater in my plant would it be profitable to install one? These are questions, the answer to which is of considerable interest to the manager or superintendent of a factory producing its own power.

As its name implies, the feed water heater is an apparatus for increasing the temperature of the feed water before it is admitted to the boiler. Generally speaking, for every 11 to 12 degrees the feed water is heated, there is a gain in heat of 1 per cent. and a corresponding saving of coal, provided the heat which warms the feed water would otherwise be wasted. The fuel saving effected by preheating feed water is shown in Table I. It will be noted that the savings effected range from 1 to 15 per cent, with 7 to 12 per cent. as the most probable amounts to be effected in practice. The table has been worked for a boiler pressure of 1 lb. as well as for a pressure of 200 lbs., and it will be seen that boiler pressure is a factor of practically no importance in the matter, inasmuch as there is only a difference of ½ per cent. or less in savings with 1 lb. pressure as compared with 200 lbs.

TABLE 1.

Fuel Saving Effected by Pre-heating Feed Water.

Increase in temperature of feed water.

	32 to 212	40 to 212	50 to 212	60 to 212	70 to 212	80 to 212	90 to 212	100 to 212	110 to 212
					Degrees.				
Boiler Pressure—					Per Cent.				
1 (one) lb.	15.48	14.79	14.08	13.35	12.60	11.83	10.92	10.12	9.32
Boiler Pressure—									
200 lbs.	14.94	14.28	13.60	12.75	12.04	11.31	10.56	9.68	8.92
					Degrees.				
	120 to 212	130 to 212	140 to 212	150 to 212	160 to 212	170 to 212	180 to 212	190 to 212	200 to 212
					Per Cent.

Boiler Pressure—									
200 lbs.	8.10	7.28	6.44	5.58	4.65	3.76	2.85	1.92	.97

Increased Boiler Capacity

The heater does part of the boiler's work. With the same quantity of coal burned a considerable increase of boiler output is assured by heating the feed water, since the latter enters the boiler with a part of its heat supplied. A greater evaporation will take place with the same amount of heat transmitted through the boiler-heating surfaces.

Thus, for example, with an initial temperature of 60 degrees, and a boiler pressure of 120 lbs., the total heat that must be supplied is 1163.6 B.t.u. per lb. of water. If, however, the feed water temperature is raised to 210 degrees, which is an increase of 150 degrees, we find that only 1013.6 B.t.u. per lb. of water is required. This is a difference of 150 B.t.u., which is equivalent to 13 or 14 per cent. increase in capacity of the boiler with the same amount of fuel.

The feed water heater reduces boiler strains and damage to boiler plates. When cold feed water is precipitated into the boiler, sudden violent strains are almost sure to occur. When the cold water strikes the hot plates the rivets may become loosened, and as the strains are local the plates and tubes may be directly injured as well as the joints become loosened. It is almost axiomatic that good service and long service cannot be had from any boiler supplied with cold feed water. The advantages of relieving boilers of the violent strains caused by the admission of cold water are not measurable by the saving in wear and tear but are nevertheless very marked.

The Economic Utilization of Steam

Efficient and inefficient engines have one characteristic in common, that is, that neither abstracts any large amount of heat from the steam. This is an important point to remember in connection with the possible use of a feed water heater and is a point directly connected with the choice of an engine and decision as to whether it shall operate condensing or non-condensing.

The answer depends upon what use can be made of the exhaust steam. Thus, if we can use exhaust steam for heating purposes, for drying materials, or in the various plant processes, the steam economy of the engine may not be important, but in preference to installing an expensive and elaborate condensing engine we may find it better economy to put in a low-priced non-condensing engine, using 30 to 40 lbs. of steam per hour and to utilize a part of the exhaust steam for the purpose of pre-heating feed water.

Classification of Heaters

Feed water heaters are generally placed in one of the following classifications:

1. Open Heaters.—In which steam and feed water mingle and the condensing gives up it heat directly to the water.

2. Closed Heaters.—In which the steam and water are in separate chambers and the steam gives up it heat to the water by conduction.

To further classify heaters, they are sometimes separated according to the pressure of the heating steam, as:

(a) Vacuum of Primary.—In this type the pressure is less than atmospheric. These are the heaters using an exhaust

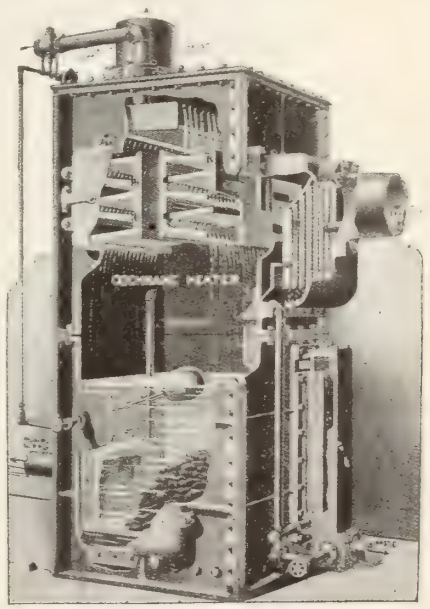

FIG. 1—COCHRANE OPEN FEED WATER HEATER.

of condensing engines and are always of the closed type.

(b) Atmospheric or Secondary.—In this type the pressure is atmospheric, or, to be exact, the pressure corresponds to the back pressure on the engine and pumps.

(c) Presure Heaters.—In this type the pressure corresponds to that in the boiler. These heaters are used primarily for purifying purposes.

Among well-known closed heaters of the atmospheric type are Cochrane, Hoppes, Stillwell, Webster, Elliott and National.

Among well known heaters of the closed type are Wainwright, Wheeler, Otis, National, etc.

Essential Requirements of Open Heaters

The principal objection to the use of

the open heater is that the oil in the exhaust steam may reach the boilers, but when the oil separator really takes out the oil, a most serious objection is removed. Therefore, the open heater should have an effective oil separator large enough to form a part of the heater and should be so designed as to eliminate all the oil before the exhaust steam enters the heater. It is not commercially practical to remove the oil or emulsion from water and the filter bed should never be depended upon for this work.

To operate satisfactorily, the oil separator should have port areas of ample size and unrestricted passage. It should be self-cleaning.

The water carrying capacity should be large; in fact, it is what really determines the rating of the open heater. Best results in purifying are assured with a large volume of water, and when there is an ample supply the fluctuations in demand for boiler feed water will cause no trouble and the boiler feed pumps will run smoothly. There should be, at least, a five-minute supply in the feed water heater, although of course local conditions may alter this amount.

The purifying of feed water in an open heater demands that the construction allow an even facility for cleaning. The interior should be accesible without disturbing piping conditions, and it should be possible to renew filter material without breaking a single connection.

The Cochrane, Fig. I, is a typical example of an open heater. Exhaust steam enters the heater through a fluted oil separator, as indicated, and passes out at the top, while the oil drips are automatically drained to waste by the suitable ventilated float. The feed water enters through an automatic valve and is divided over a series of copper trays, so arranged and constructed that the water is forced to fall in a finely-divided stream before reaching the reservoir in the bottom. The steam, coming into contact with the water particles, gives up latent heat and condenses. Some of the scale-forming element is deposited on the surface of the trays from which it must be removed. The suspended matter is eliminated by a coke filter in the bottom of the chamber and the floating impurities are decanted by a skimmer or overflow weir. The particular heater shown in the illustration is especially designed for use in a steam heating plant, i.e., besides performing all the functions of an open heater it provides for the reception and heating of the condensation returned to it from the heating system.

Fig. II. shows a section through a Hoppes open heater, illustrating the "pan" type. Exhaust steam enters at H, passes through oil filter first and completely surrounds pans T, T. The feed water enters at B, and the rate of flow is regulated by valve F, which is controlled by a suitable float in the lower part of the chamber. Water, in flowing over the sides and bottom of the pans comes in direct contact with the steam. The National heater is illustrated in Fig III, which shows the oil separator of the same diameter as a shell of the heater, forming its back head.

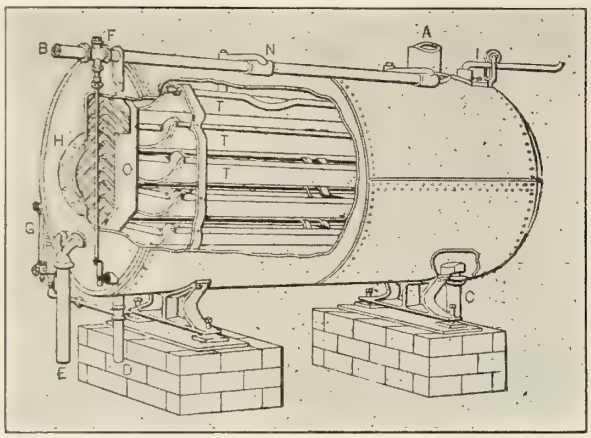

FIG. 2—HOPPES HORIZONTAL FEED WATER HEATER

There is very little of special moment which can be said with regard to the performance or economy of any particular make of feed water heater as compared with the others. Any open type feed water heater in which the sizes of openings are properly designed to admit steam and water and to discharge water, and which has a proper arrangement of perforated trays for breaking up the water for close admixture with the steam, will utilize all of the exhaust steam possible and will increase the temperature of the entering water to a temperature within two to five degrees of the temperature of the steam which is used for heating the water.

There are other possible economies to be obtained from the use of a feed water heater besides that of heating feed water; such, for instance, as the retaining of solids made insoluble at the temperatures of the hot water within the heater rather than to let these solids go on to the boilers. There are various constructions on the market for which it is claimed that a large quantity of such solids will be retained in the heater, but the truth of the matter is that the largest part of these solids cannot be retained on the heating trays or in the filter section of any of the so-called standard types of heaters. It is necessary to provide a water storage capacity of such volume that the heated water may remain practically motionless for a period of one-half hour to one hour before any real depositing action will be obtained in the feed water heater. Such a construction means a tremendous use of valuable floor space or head room in the power plant for the installation of such a storage compartment and is usually not considered economical practice except where the water conditions are unusually bad.

Closed Heaters

What of the closed heater? The essential requirements of the closed heaters are as follows:

1. That they may be easily and thoroughly cleaned.
2. To heat the feed water to the boiling point without causing any back pressure.
3. That they will not foul with scale if properly taken care of.
4. That they will separate and carry off the water of condensation from waste.
5. That they will extract the oil from the exhaust so that the steam can be used for heating purposes and the condensation from the heat coils be returned to the boilers without injuring them.
6. That they will collect and carry off any scum on the surface of the water.
7. That they shall be so constructed that any individual tube can contract and expand independently of the others.
8. That they be made of the best materials and be thoroughly tested before leaving the factory.

Fig. 4 illustrates the Wainwright heater. The body of the heater is cast iron and the tubes of corrugated copper. The water passes through the tubes and the steam surrounds them. The feed water and exhaust steam do not mingle, and hence the oil in the exhaust does not contaminate the water. Water chambers are divided into several compartments, as shown in the illustration, and the partitions are so arranged that the flow of feed water is directed back and forth through various groups of tubes in succession. This arrangement gives a higher velocity of flow than the non-return of heaters and therefore increases the rate of heat absorption. The mud and impurities settle at the bottom and are discharges through the mud blow-off, and such impurities as rise to the surface are removed by the surface blow-off. The tubes are corrugated and allow for expansion and at the same time increase the transmission of heat.

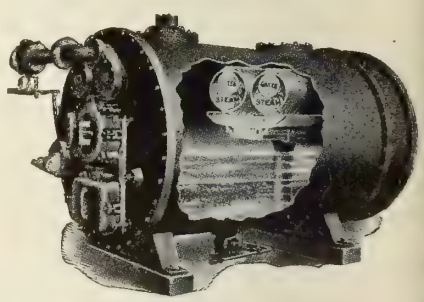

FIG. 3—NATIONAL OPEN HEATER.

In the National closed heater, which is not illustrated, efficiency in heat transmission is secured by the use of a small curved or coiled tube in increased frequency of contact the particles of water with the wall of the tube. Even distribution of the water to the tubes is secured by the large manifolds or tube chambers into which the ends of the tube coils are expanded. The tube ends are accessible through their plugged holes on the top of the tube chambers in the large heaters.

One of the most common experiences in connection with the operation of closed heaters is to find them leaking water from the bolted flange joints. Upon inquiry in such cases one is invariably informed that it is not always an easy matter to pack the flange, it being a job that must frequently be done on Sunday or at night. In nearly all such cases it will be found that the leakage is due to the fact that there is no relief valve to take care of the increased water pressure caused by heat and expansion when the feed water valves are closed. It has been found that the pressure of the water when the feed water valves are closed will, at times, reach a pressure of 500 lbs. In such circumstances the importance of the relief value can be readily appreciated, and it will be found that the use of such a valve will remedy the cause of closed heater leakage.

Open Versus Closed Heaters

Which shall it be, the open or the closed heater? Each type has its advantages, and heaters of both types are made by a number of concerns. A careful study of the particular plant conditions for an intelligent choice is necessary. The following parallel comparison brings out a few of the important factors:

Open Heaters	Closed Heaters
Efficiency	
Feed water may be brough to same temperature as the steam, by employment of sufficient exhaust steam.	Feed water will always be two degrees or more lower than the temperature of the steam.
Scale and Oil	
Do not effect the heat transmission.	Will lower the heat transmission.
Pressure	
Seldom subjected to more than atmospheric pressure.	Water pressure slightly exceeds that in the boiler as it is customary to place closed heaters on pressure side of the pump.
Safety	
Sticking of the back pressure valve may cause the open heater to blow up if provision for relief is not made.	Will safely withstand any pressure likely to occur.
Purification	
Oil in exhaust steam comes in contact with feed water and must be removed.	No oil comes in contact with feed water.
Removal of Precipitate	
Scale and other precipitate readily removed.	Scale and precipitate removed with difficulty.
Location	
Must always be placed before the pump suction on the suction side.	May be placed anywhere on the pressure side of the pump.
Pump	
With supply under suction, two pumps are necessary and one must handle hot water.	One cold water pump necessary.

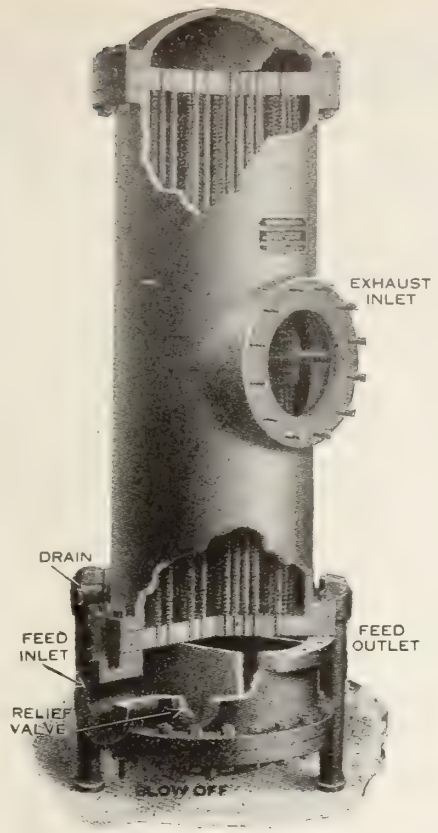

FIG. 4—WAINWRIGHT CLOSED HEATER.

A further advantage for the open heater claimed by manufacturers of this type of equipment is that there is a marked saving in water. Thus, in the open heated 6 lbs. of water and 1 lb. of steam combine to make 7 lbs. of feed water, but in the closed heater there is no mingling of the steam and water, consequently 7 lbs. of water and 1 1-6 lbs. of steam are required to produce the result. That is to say, the closed heater uses 14 per cent. more water than the open heater. This point may be important in some plants and of no moment in others. Finally, the thing to be emphasized in connection with the prospective purchase of heaters is, first, that such equipment makes for economical operation, and second, that the proper choice of the heaters will depend upon individual conditions.

C. A. S. E. CONVENTION

Continued from page 275

above the town, on one of the highest spots in that part of the country. We would recommend the visitors to the convention to take a drive up to this spot if the weather is clear, and enjoy the beautiful scenery which is unfolded below. It is truly a delight to the eye.

The reservoir was built in 1906, and has a capacity of 1,000,000 gallons. It was originally built in one part, but in order to facilitate cleaning, a dividing wall was later built across it. In order that those in the station may know if the water has reached the high level when pumping up, or the low level when pumping has not been done, an electric alarm is installed. This consists of two diaphragms, to which are connected rods, and the variation in the pressure caused by the varying height of the water above the diaphragm will force it up or allow it to come down, making or breaking the circuit, which lights a lamp in the pumping station.

Looking down from the walls of the resorvoir, one gets an excellent idea of the clarity of the water. At a depth of twelve feet, the bottom can be seen as plainly as if there were no water there. Woodstock is certainly fortunate in her water supply, and the only fly in the ointment is the fear that with the expansion that must come to the city, the supply will not be adequate. However, that is a fear for the future. It is interesting to note that while in 1885 the mains had a total length of 6.3 miles, and the hydrants numbered 60, at the end of 1917 there were 20 miles of water mains, and 175 hydrants, and these are being added to as occasion requires.

Before closing this article the writer wishes to express his gratitude for the courtesy extended to him by Mr. J. G. Archibald the superintendent of the water works.

PERSONAL

Mr. W. Reese of Hamilton, has lately returned from England, where he secured the selling rights for Canada for the British Hele-Shaw Patent Clutch Co., of Oldham, England, and the W. R. Patent C. O_2. Recorder Co., Leeds, England. Mr. Reese spent four years in England during the war, being engaged on the testing and treatment of materials for heavy artillery in the inspection department of the British Ministry of Munitions. Previously he was for 8 years master mechanic of the Consolidated Mining and Smelting Company, at Trail, B.C., and Rossland Mines, B.C.

We have received bulletins descriptive of the "Universal Unaflow" engine, built by the Skinner Engineering Co., Erie, Pennsylvania. One of these is devoted to the economical aspect of the engine, and several diagrams are shown comparing the performance of the "Unaflow" under different conditions of steam pressure and superheat, condensing and non-condensing. Another of the bulletins is devoted to examples of the "Universal Unaflow" in actual service at various plants, and the results achieved by them. A third bulletin describes the principle on which the Unaflow engine is designed, its history, details of construction, and steam distribution.

Messrs. Burlingame and Gardner who have taken up the manufacture, installation and sale of the Bernitz method of furnace lining, have secured office location at Room 110-123 Bay street, Toronto. The firm will occupy their new office premises about the middle of June.

THE THIRTY-FIRST CONVENTION

BEFORE the next issue of Power House is off the press, the 31st convention of the C.A.S.E. will be a matter of history. The programme for the three days is before us as we write this, and if all the events featured on that are carried through, there are three strenuous days ahead of the delegates, their wives and families.

It is rather interesting to note that the purely engineering side of the convention seems to have been pretty well side-tracked. The exhibitors of engineering supplies and specialties will be on hand, and a strong exhibit is assured, but for the delegate who attends the convention hoping to gather something of educational improvement, there is little provision made. What the reason is we are not sure, but possibly it is on account of the small amount of interest displayed on past occasions to this side of the convention. Stationary engineers are a class whose nose is kept pretty well to the grindstone, and it is perhaps natural that they should wish to make the convention a time of play instead of a serious effort. This is quite in order but it seems that a little more time could have been devoted to the reading and discussing of papers than has been allotted, without unduly interfering with the lighter side of the programme.

In the majority of cases the meetings and conventions of the different engineering societies devote the greater part of their time to the advancement of the engineering knowledge of their members. This devolves to the benefit of the engineering world in general, through the publication of their deliberations in the technical press. It would seem that a gathering composed of delegates from the various lodges of the C.A.S.E., men who are encountering operating problems of all kinds and in all sorts of plants, should have a wealth of experience which they could give for the benefit of their fellows. It is through problems arising in every-day operation, and the efforts to overcome them, that most of the improvements in steam engineering come about.

Apart from the actual operating of steam plants, one would have expected to see stationary engineers taking an interest in general engineering developments. The fuel situation, and its probable effect on future conditions, the development of Hydro-Electric power, the coming of the internal combustion engine, and the probable field before it, are all matters of vital interest to the power plant man. What better opportunity can he wish to discuss these matters than at a gathering of representative men of his own class drawn from all parts of the country.

These are matters, undoubtedly, worth consideration, and while it is true that all work and no play makes Jack a dull boy, there is no time when play can be better enjoyed than after work well done.

The visitors will find Woodstock a pleasant city to visit, and the members of the local lodge and the citizens generally are anxious to give the convention a warm reception. The convention hall will not be quite as warm as was the hall at last year's convention, but perhaps no one will mind that. We are pleased to see that the name of A. M. Wickens, the grand old man of the C.A.S.E., is on the programme, and we hope that it will be prominent at many more conventions.

We look forward to meeting many old friends and making many new ones between June 22 and 24, and feel sure that after the event we shall be able to write in the classic phrase of the country correspondent, "A pleasant time was had by all."

THE UNIFLOW ENGINE

THE Uniflow type of steam engine, though a comparatively new comer to the ranks of prime movers, is making some very strong claims to consideration. The European practice has been chiefly to design these engines for condensing operation, and some very fine results in steam economy have been obtained. It is claimed to be more economical than the triple expansion engine, with the advantage of being contained in one cylinder. On this Continent the practice is largely to run non-condensing, due to the heating necessary over a large part of the year. This necessitates some modifications in the design, to relieve the extra compression which takes place in these designs when exhausting at atmospheric pressure. An engine built in the United States for both condensing and non-condensing loads, has achieved some remarkable results, the steam consumption at full load being 13.8 pounds per I.H.P. per hour when condensing, and 18.8 pounds when non-condensing. It would seem that here we have a worthy representative of the steam-driven class of prime movers, and the competition that is beginning between the steam-driven type and the internal combustion type should be of great value in ensuring the conservation of natural resources. Every improvement made in either is a clear gain to the whole world.

An idea of the amount of money the people of New York City are spending for amusement can be gleaned from figures made public by William H. Edwards, Collector of Internal Revenue, which show that the theatres of Manhattan collected $783,891.42 in war taxes during January and $695,626.70 in February. The tax on all theatre tickets is 10 per cent., so Mr. Edwards' figures indicate that the income of Manhattan theatres during January was $7,838,914.20 and the following month it totalled $6,956,-267. The collector declared his office checks up all box office receipts and that the auditors have not discovered any attempt to cheat Uncle Sam.

Programme of the C.A.S.E. Convention June 22, 23, 24

Tuesday, June 22

10.30 a.m.—Meeting Executive of C.A.S.E.
2.00 p.m.—Meeting Executive of C.A.S.E.
—Exhibition open all day.
8.00 p.m.—Movie show for ladies, guests of Woodstock Lodge.
—Educational session and smoker (men only), with smokes supplied by local lodge. Geo. E. Moll, chairman.
—A few parallel lines by W. H. Auger.
—Combustion Engineering by Hartley B. Gardner, with the discussion opened by A. M. Wickens.

Wednesday, June 23

9.00 a.m.—Meeting C.A.S.E. Executive.
—Exhibition Hall open morning and evening, but closed in afternoon for the picnic.

Wednesday Afternoon, June 23

2.00 p.m.—Auto drive around city by Woodstock Automobile Club from Exhibition Hall.
2.30 p.m.—The engineers and their friends will be entertained at Southside Park, Woodstock, by the Exhibitors' Association. Ice cream and lemonade will be served during the games. Let all the engineers bring their families. The more the merrier.

1.—Association football, Engineers vs. Supplymen.
2.—100 yard dash (open).
3.—50 yards race for the wives of engineers.
4.—Wheelbarrow race for men.
5.—Clothespin race for ladies.
6.—Donkey race for men.
7.—Soap race for married ladies only. Ladies keep the soap they secure and the one securing the greatest number will be given a valuable prize.
8.—Peanut race for unmarried ladies.
9.—Men's smoking race.
10.—Little boys' race.
11.—Skiff race (singles).
12.—Canoe race (singles).

Director of games, E. B. Curzon, assisted by Geo. E. Moll.
Presentation of prizes by President J. S. Mock at the conclusion of the games.

Wednesday Evening

The Exhibition Hall will be open until 8.30 to permit the members of the Grand Lodge and others to examine the exhibits.

8.30 p.m.—Entertainment in the City Hall. The program will start exactly on time.

1.—Speech by Mayor A. J. Gahagan, chairman. The Mayor will be introduced by J. S. Mock, president of the Exhibitors' Association. After his speech, Geo. E. Moll will reply.
2.—Solo by William Coutts.
3.—Solo by Miss Doris Leggo.
4.—Solo by Bob Jones, New York.
5.—Comic by P. Wilson.
6.—Song by Harry Curtis.
7.—Vocal by Miss May McCauley and Mrs. Sticker.
8.—Solo by E. B. Curzon, Montreal.
9.—Comic by Mr. Downs.
10.—Song by Earl F. Hetherington, Galt.
11.—Speech by the celebrated New York orator, Jack Armour.

(There will be no encores).
Heintzman piano kindly loaned by Ye Olde Firme Heintzman & Co., Ltd.

10.00 p.m.—Prize drawings. Everyone registering has a chance to win a valuable prize.
Ladies' lucky numbers are 1, 3, 7, 11 and 15.
Men's lucky numbers are 1, 4, 8, 13, 19 and 23.
Drawings will be made from a hat by a young lady chosen from the audience.

10.30 p.m.—Dancing.
—Buffet refreshments supplied by the Exhibitors' Association.
—Miss Watson's Orchestra.
The badge will admit to the City Hall. Badges may be secured by registering at the Exhibition Hall adjacent to the City Hall.

Thursday, June 24

9.00 a.m.—Meeting C.A.S.E. Executive.
10.30 a.m.—Annual meeting Exhibitors' Association.
2.30 p.m.—Installation of officers of C.A.S.E. Executive.

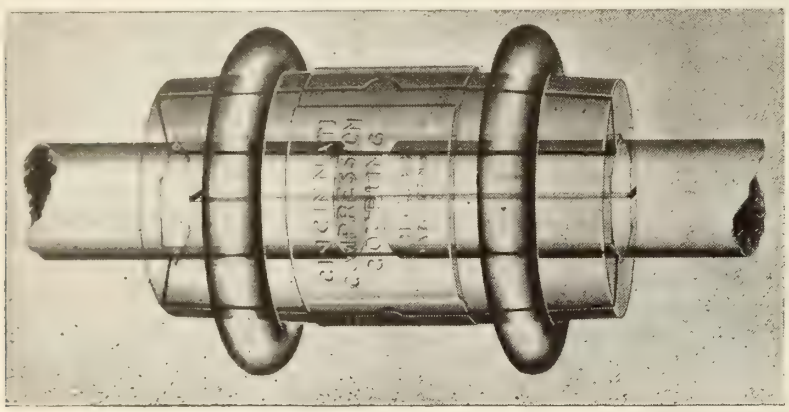
In 1919 Ontario had fire losses of $9,500,000. These were manufacturing places, 447 fires at a loss of $2,275,000; stores, 1,008 at $1,900,000; dwellings, 5,695 at $1,650,000, and farm barns, 748 at $1,100,000. Officials say that fully half of these were from pure carelessness. We are certainly paying a fancy price for letting our ears grow long.

JAMES S. MOCK,
President Exhibitors' Association.

Progress in New Equipment

NEW COMPRESSION COUPLING

The Cincinnati Ball Crank Co., Cincinnati, Ohio, have placed on the market a new type of compression coupling for use in connecting line shafting. The



VIEW SHOWING CONSTRUCTION OF COUPLING.

illustration herewith gives one a good idea of its appearance and its outstanding feature is simplicity. It can be installed on any kind of shaft in five minutes' time. It is adapted for use in every industry where power is transmitted by means of line shafting.

The construction of this new coupling constitutes a radical departure from the old type flange and bolt connection. It consists of five pieces—three jaws, and two clamping rings. The jaws of the coupling are placed in position about the shaft, and held in place by the longitudinal grooves and notches that lock them together. The forged clamping rings are pushed on over the tapering ends of the jaws, and hammered tight.

A hammer is all that is required for installing the coupling—no dismantling or machining of the shafting is required. It is only necessary to have sufficient clearance between the two loose ends of the shaft to allow the passing of the clamping rings.

The coupling grips the joined sections of the shaft, holding them in alignment. The round, machined sections of the tapered end of the coupling jaws form lines of contact for each ring, and once driven into place it is impossible for the coupling to become loose. It is stated that many of these couplings have been in use three years without a single adjustment since they were installed.

The assembled coupling forms a clean, compact shaft joint. There are no projections on its outer surface to catch a workman's clothing. When used as a reducing coupling, the only additional parts needed are three strips of cold rolled steel to fit between the smaller shaft and the inside of the coupling jaws. These couplings are made in sizes from 15/16 to 3 inches.

SMOTHERING THE FIRE

Fires are something which are much to be avoided, and all precautions are generally taken to eliminate them, yet we are well aware that they persist in cropping up in spite of all precautions.

The next best thing is to be prepared for the fire when it does come, and on this assumption the Canadian Firefoam Co., Hamilton, Ont., have placed on the Canadian market what is known as Foamite Firefoam. To illustrate the uses of this product they have issued a very attractive booklet, entitled 60 seconds and out. They show various instances of fires, and how they were extinguished by means of their product. One outstanding example is a huge 55,000 barrel tank fire at its height. In spite of a strong wind this fire was smothered in 48 seconds, or less than one minute after it had reached its worst.

Briefly, the principal of firefoam is as follows: It is based on the well-known fact that carbonic-acid gas is fire's most deadly enemy. Cover any burning surface with this gas and the fire is quickly smothered. Working on this fact, firefoam was so constructed that the gas was kept over the burning surface in the form of millions of minute bubbles.

The illustration herewith depicts what is termed their 40-gallon Foamite Firefoam engine, and its contents expand to 320 gallons of firefoam upon release. The contents can be discharged on any burning surface at a distance of 50 ft. or more. The type of engine shown is one recommended for plants, buildings and other places where hand extinguishers would be of insufficient capacity.

Larger engines of 250, 500, and 800 gallons and upwards are made, all depending upon where they are to be used. Hand extinguishers and fire pails are also handled by this concern, all equipped with the Foamite Firefoam.

One particular advantage, as claimed for this product, is the fact that the

THIS VIEW ILLUSTRATES THE 320-GALLON CAPACITY ENGINE.

foam is comparatively dry compared to water, therefore resulting in less damage. The use of this material is not confined to oil fires, but to fires of any nature in the industrial world.

Extend Working Day.—Canada Foundries and Forgings, Limited, announce that their Canadian Billings and Spencer plant at Welland, after two weeks shut down on acount of strike, has once more resumed operations in full; the Employees having agreed to the company's terms, which include an extension of the working day from an eight to nine hour basis.

OFFICERS OF THE EXHIBITORS' ASSOCIATION, C.A.S.E.

Business Conditions Are Sound

BUSINESS conditions in United States and Canada are fundamentally sound. Circumstances are not the most favorable, and there are many troubles that will not be removed for weeks and months to come. But, allowing for all that, there is nothing of the blue-ruin type in sight.

A representative of this paper attended a meeting of the Editorial Conference of Associated Business Papers in Chicago last week, where business conditions in all the fields represented were discussed by experienced business editors who were in close touch with the trade in their varied fields.

Many of the speakers made the point that the railway situation in United States, following the switchmen's strike, was the root of the trouble. The strike had been a vicious attempt to paralyze the nation's business in the shortest possible way, and for a time success was with the strikers. Canadian industries have a lot of raw material coming from United States. They can look for improvement before long, but the improvement will not be sudden, and it is likely that many months will pass before traffic is passing with the necessary speed between points in the two countries.

One point was brought out that shows a wheel within a wheel, in that the inability of the railroads under present circumstances to transport material to the shops making cars and engines would delay rapid recovery in the railroad problem. In other words, the poor physical shape of many of the roads is making it hard for them to help themselves.

The iron and steel industry has a large volume of perfectly good business on its books. Production is now around 75 per cent. of capacity, but when it is considered that capacity increased some 40 per cent. during the war, it will be seen that 75 per cent. production now is really greater than 100 per cent. capacity in the pre-war days.

The lumber trade reported declining markets, but there were factors that had been in operation to keep the markets from being filled up when these declines were on. Strikes and poor weather had kept the cut down. One expert on the situation claimed that the policy of the larger dealers in a declining market is to force the situation as much as possble and reach bottom at once, depending on past experience of reactions after sharp declines to bring them safely out of any troubles.

The feeling was also expressed that stability could be lent to the present situation in a marked way by a feeling that prices had gone their worst. Of course, there are exceptional cases where this cannot apply. In the main, though, it is worth serious consideration. Several cases were cited where large projects were hung up for the present, because those behind them were not inclined to go into the market for building or equipment, because they knew that costs would be so high that they would be unable to compete with the product of plants that had been built in pre-war times.

Business and banking circles reported that credits were being tightened rather than extended, but they claimed that the general effect was regarded as good. Makers of touring cars were being notified to cut down on their output, while builders of trucks and tractors were being assisted to go ahead. The reason was that the building of the latter would result in a greatly increased area of land being worked on the farms, and thus the new wealth of the country would be added to from year to year.

In all the reports that were delivered, there was nothing to shake confidence, or to cause one to feel that the future had in store anything that sane commonsense could not surmount.

The Use of Chain Drives on Grooved Drums

This Article From "Practical Engineer" Emphasizes the Importance of Studying Lead of Chain Before Going Ahead With Layout of Drive, in Order to Minimize the Wear on the Chain and Drum

By G. H. Roberts

THE lead of a chain or rope from a grooved winding drum is a matter which, in the opinion of the author, is seldom given the full attention and consideration that it should have, with the inevitable result that when haulage takes place much more wear and tear occurs on the chain, drum, and fair-lead than would actually be the case if greater thought had been given to the original lay-out of the arrangement. While admitting that site conditions or requirements do not always lend themselves to the ideal scheme, as referred to later, nevertheless a better compromise between theory and practice could have been applied to innumerable saving in wear and tear and considerable saving in wear and tear effected, with its consequent increase in life of the various parts directly affected.

Before dealing with the different chain leads, it may be advisable to briefly refer to certain features in regard to the drum itself, and also the chain. The diameter of the drum has much to do with the useful life of the chain, and, although there appears to be no predetermined or recognized ratio between the two—as there is in deciding the minimum diameter over which a steel rope should work—still it should be kept as large as circumstances will permit. If too small a diameter drum is introduced with heavy loads, the links will be subjected to considerable distortion in their attempt to adjust themselves to the surface of the drum barrel.

Fig. 1 shows in a slightly exaggerated sense the tendency of the horizontal links to bend when stressed in working. Theoretically this condition will always occur, no matter how large the diameter of the drum or sheave, but the possibility of fracture in the link through this cause will practically disappear if reasonable sized drums and short-link chain are used in conjunction with heavy loads.

Again, the length of the drum may have something to do in settling its diameter, as the whole should be so designed that any possibility of the chain coiling up on itself is obviated. A long barrel is objectionable, as will be observed later; this, however, should not be cut so fine that no latitude is provided for an additional coil or two—this should always be allowed for, even though the need appears unlikely to arise when the machine is in use. Two or three "dead" turns are frequently provided for at the fixed end of the chain; these, as the name implies, never pay off, their duty being to relieve the stress on the anchorage and prevent any irregularity at the beginning of the haul. The "live" coils are those whose total length are equivalent to the possible travel of the load. The length of the drum is therefore made up of three distinct parts, as indicated on Fig. 8. With regard to the grooving, care must be taken that the running clearances are no more than actually required; if the channel is made too wide, an insufficient seating is obtained for the links, and they are likely to bind in the groove, as shown in Fig. 2. There is always a tendency for a chain to do this, due to the twisting effect which occurs when winding begins. Cast grooved wheels are the greatest defaulters in this respect. In Fig. 3 are indicated four of the most common chain lead arrangements, where a fair-lead wheel is introduced to deflect the chain in the desired direction. These are enumerated as follows :—

(A) Horizontal lead with pull downwards.

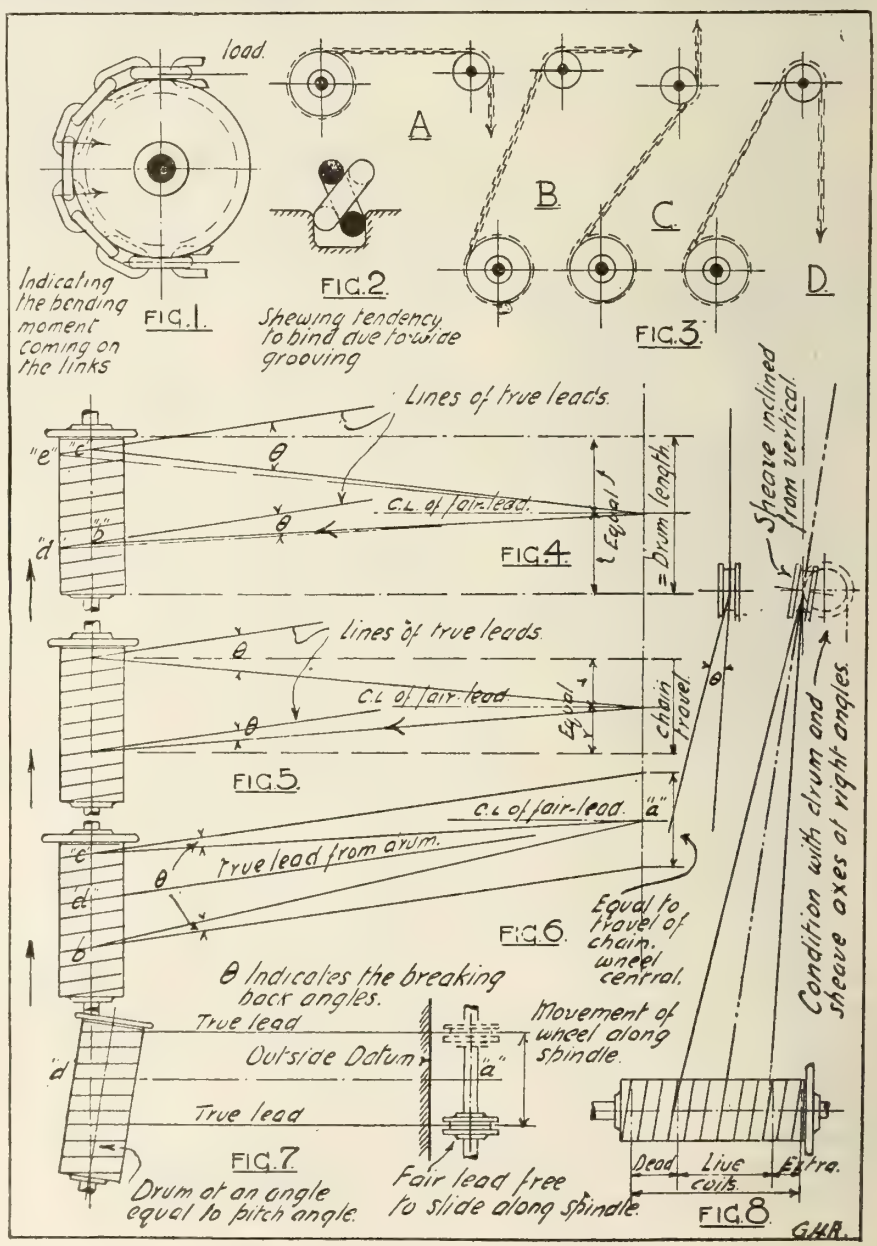
(B) Inclined lead with horizontal pull.

(C) Inclined lead, chain deflected upwards.

(D) Inclined lead with downward pull.

There are, of course, other arrangements, but the foregoing will be sufficient for the purpose of this article.

With diagram A it will be found that in numerous cases the relative positions



in plan of drum and lead wheel will either be as Figs. 4 and 5. What is the effect on the chain and grooving ? In Fig. 4 the fair-lead has been placed practically central with the total length of barrel, winding being in the direction indicated by the arrow head. Assuming that, say, three "dead" turns have been allowed, then at the beginning of the haul the chain follows the line a b, and at the end of the full travel will be as a c. These, as will be readily seen, do not represent the true lines of force, these latter geing respectively a d and a e, and to which the chain is continually trying to align itself, but prevented from doing so by the grooving in the drum. The detrimental effect of this is at once apparent, the resultant pressure increasing as the chain works its way along the drum, as will be observed on reference to the diagram in question. As a result, excessive friction and wear to the groove sides and the links is constantly taking place, and the heavier the load the greater will be the adverse conditions under which the machine will have to work. In Fig. 5 an improvement is made. Here the lead wheel occupies a position central with the total travel of the chain along the drum. This reduces the breaking-back angle o, and consequently lessens the wear and tear on chain and grooving. Scheme 6 represents the best practical solution with a fixed lead sheave, i.e., a sheave limits of chain travel along the barrel having been settled, the distance between is halved and a line produced parallel to the helix line of the pitch angle, as a d, point a being the first point of contact with the guide sheave. If points a, b, and c are now triangulated, it will be observed that the breaking-back angle at start and finish is considerably reduced, while at mid-travel a perfectly true lead is obtained. The working conditions on drum and sheave are therefore very much improved by this arrangement. Where the fair-lead can have freedom to slide along its spindle, and the lead is also free to adapt itself to varying horizontal positions, then a very satisfactory arrangement is arrived at, and one which can be further improved if the spindle of the sheave is moved round until it is at right angles to the chain lead, as indicated. This considerably reduces the running friction between sheave and spindle, the only wear now occurring being due to the sliding action along the shaft. If such an arrangement of guide sheave is applied to the former examples, it will undoubtedly help matters, but never entirely eliminate the breaking-back of the chain as it winds on or off the drum. The three diagrams just described are drawn to the same scale, so that they indicate proportionately the different conditions, the pitch angles being increased for the sake of comparative clearness.

Fig. 7 illustrates the practical application of Scheme 6, wherein the winding drum is shown moved round until the lead wheel spindle is parallel with the outside datum.

For various reasons it is not always practically convenient to apply the last scheme on the skew, as indicated, because, as a general rule, the lengthwise centre line of the machine must be at right angles to the loading face, taking an ordinary runway cat-head hoist as a case in point. In order to meet such requirements and still maintain arrangement No. 6, it is adjusted until the centre line a d is in the desired position, the angle through which it is moved being, of course, equal to the pitch angle, as shown in Fig. 7. The drum now occupies the angular position, but this, in the majority of cases, will not be found a practical objection ; generally the other parts of the gear and supports can readily be arranged to meet this particular feature.

Considering now the three remaining leads B, C, and D, it will be noted that the scheme shown, Fig. 6, still retains superiority over the other two, although with an inclined or vertical lead to sheave; skewing the drum on its base a small amount does not help matters much, but if it is turned round until the axes of drum and sheave are at right angles to each other, then the conditions illustrated in Fig. 6 with fixed sheave are obtained, with the added advantage that no breaking back on the sheave groove occurs. This relative arrangement of drum and wheel, as will be conceived, is equally applicable whether the chain is led upwards or horizontal or has a downward pull. With parallel axes there will always be a certain amount of breaking back on the fair-lead sheave; this is unavoidable. But with a fairly long lead between drum and sheave this does not amount to much, and is to all intents and purposes practically the same in all the cases referred to. The fixed sheave could, of course, be inclined to suit the central lead, if so desired, but no real practical purpose is served in doing so unless the chain has to follow such paths as indicated by the chain-dot line in Fig. 8, and then circumstances must decide if such a modification is necessary.

Too often conventional methods are blindly followed, with the result that Schemes 3 and 4 are continually perpetrated ; the introduction of arrangement 5 may disturb previous routine, but it is a good thing to create a precedent sometimes that has distinct advantages.

EDITOR, *Power House*,

Sir:—

Now that coal has reached the price it has, should not school boards or city councils appoint men, who are experts in the construction of heating apparatus, also who have made a study of the combustion of coal, to act as inspectors for the schools and public buildings of our cities, as a means for reducing expenses to the School Boards and ratepayers. Also as a means for the conservation of our coal. Which cannot be denied is of most vital importance.

It is possible that the heating systems for such buildings are managed by faithful men, but as any handy man can handle a shovel it cannot be denied but that many are appointed as caretakers and firemen that have not the practical experience necessary in order to obtain the highest rate of efficiency from their plants. At least this is the opinion I have formed after a life's experience in the heating trade, which has often brought me in close contact with many heating systems in such buildings.

Very many furnace rooms of such buildings, I have gone into where I have noticed from 25 to 50 per cent. of the coal used, going to waste. There are so many causes where such waste can come from that when these are added together, tests have proved the truth of my statement to be 25 to 50 per cent.

The fault was sometimes in the method of firing the furnaces. In others, due to the deterioration or unsuitable equipment, but in most cases, a combination of both.

Many men who fired furnaces in such buildings when coal was less than half the price it is to-day, are still resorting to their antiquated or old time methods of firing. How is it possible to reduce the coal consumption under such conditions. A few visits from such an inspector would soon enable them to see where they could save unnecessary labor for themselves, also coal for their department.

Then there is the equipment. In many cases, even if the caretaker is a practical engineer his suggestions for repairs, or slight alterations are not considered seriously, or it may be taken that as he is not an expert, he may be asking for something that is not necessary. But in the case of a practical inspector, who is working to show results of his office, matters would be very different.

Such a man would find his time fully occupied all the year round. During summer he could make thorough examinations of every part of each system. See that the condition of each boiler, also furnace was such that there would be no loss of heat generated from the coal, and that top notch efficiency could be obtained when buildings required heat. During the winter to give practical instructions and demonstrations on firing to prevent waste of coal or the products of combustion.

There is not the least doubt in the writer's mind but that such inspectors salary would be saved many times over by the saving of coal, which may yet reach such prices that it will be necessary to further increase the rate of taxation, and cause less coal for those who come after us.

J. G. KINGSTON.

For the purpose of clearing away the debris in the headings of a tunnel being constructed in California, steam navvies worked by compressed air are being used. The tunnel, 3¼ miles long, is for a hydro-electric scheme, has a section 17ft. by 17ft., and is driven largely in solid granite. The shovels have dippers of 21 cubic feet capacity on 13ft. booms, and, on the average, clear away the 150 cubic yards of rock brought down at each blast in eight hours.

Recent Developments in Oxygen Cutting*

IN presenting the most recent developments in the art of cutting with oxygen we have concluded that the most interesting development which has occurred recently in connection with cutting is, without doubt, the successful cutting of cast iron.

More than a year or two ago, there were rumors heard now and then in the industry, of some genius who stated that he had cut, or could cut cast iron. These rumors were not given much credence because it was thought that in most instances the man who believed he had cut cast iron had, in reality, cut something else which he thought was cast iron.

About this same time our Engineering Department began to think more deeply upon the subject, with a view to learning more of the basic principles underlying cutting, particularly with respect to cast iron. We began to experiment and detailed Mr. F. J. Napolitan to the work. He has continued his efforts in this direction, until we believe he has developed some very interesting theories, and has evolved some principles which are of extreme importance to the art. In compiling this paper we have worked together to lay before the Society, an outline of these theories and principles, which we believe will be of interest, and which may explain some of the conditions well known by men practised in cutting, but which had never been clearly understood by the majority of cutters.

When we succeeded in cutting cast iron, it must disturbed our dignity in that we were obliged to reverse our former opinions and beliefs, and to take back the statement often made, that cast iron could not be cut with the oxy-acetylene torch. Unfortunately, our experiments are by no means concluded, so that we are not free to disclose all that we would desire. Frankly, our investigation of cast iron cutting was inspired by nothing more noble than to seek a better explanation of why cast iron could not be cut. Most of us, and I am no exception, have expressed at some time or other in our experience, the solemn opinion that cast iron could not be cut, because the oxide of iron melted at a temperature higher than cast iron itself. Not only does cast iron burn to form an oxide, but the higher melting point of the oxide probably assists the reaction.

While we are rather skeptical of the commercial value of a cast iron cutting torch, and are convinced that, financially, we will never be repaid for the expense of our experiments, yet there are undoubtedly occasions when the cutting of cast iron would be of great value. In the ordinary scrap-yard, or in instances where the cutting process would be used as with steel, it is so easy to break cast iron, that it would hardly be economic to use the cutting torch. Were we not to further develop cast iron cutting, however, we should feel remiss in the work of our Engineering and Research Department.

You are all aware, of course, of that application of oxygen cutting used largely in blast furnace practice, the opening of a "frozen" tap hole. You could not quite reconcile this more or less common application of the process with the pet theory that cast iron could not be cut.

One of the usual methods for releasing a frozen tap hole in a blast furnace, is substantially as follows: A piece of one-quarter inch iron pipe with a brass handle, at least ten feet long, is attached to a manifold of several oxygen cylinders. Oxygen is delivered through this pipe at a pressure of approximately 100 pounds per square inch. A hole is started with a star drill or diamond point, until it is about three inches deep. The metal adjacent the hole is heated with a fuel oil burner or by other means. The end of the iron pipe is ignited and the composite stream of molten iron slag and oxygen caused to impinge against the frozen cast iron.

A spectator to this performance of infernal fury, is readily convinced that the heat is not all due to the combustion of the wrought iron pipe, but that the cast iron is burning with a violence equal to that of steel. This reaction inspired some inventors to incorporate a device in an oxy-acetylene torch for cutting cast iron, which would feed a steel wire between the cutting jet and the cast iron piece being cut. Ignition of the wire carried a stream of molten slag on to the cast iron and it was hoped thus to propagate the cut. In a second process, a plate of steel of definite and predetermined thickness, was placed on top of the cast iron. It was hoped that the slag incidental to the oxidation of the steel, would exercise some influence over the cast iron and enable it to be cut.

Unfortunately for those responsible for the exploitation of these devices, the inventors were more concerned with converting cast iron into iron oxide by means of the oxy-acetylene torch, than they were in constructing a practical process and a practical tool. It was next proposed to simplify the reaction by supplying an apparatus with a mixture of pulverized slag and iron powder, and in fact a number of patents were issued covering various applications of such a device. Crude and elementary as such devices were, they actually produced combustion of the cast iron and went a long way in stimulating us in our endeavors to find a successful method.

Experimental work was continued with a torch having a good many different tubes leading to the head, so that almost any combination of gases at varied pressures might be obtained. Mr. Napolitan has evolved from these experiments, interesting theories pertaining to the reactions which take place in cutting, together with their relation to our success in cutting cast iron. He has noted these theories in the article which follows. We are presenting these theories for what they are worth. We can actually cut cast iron and we do it by *preheating the oxygen.* We have endeavored to tell our conclusions pertaining to the reactions which take place. We will now take up the subject of metallography of iron and steel with reference to oxygen cutting.

Points Discovered

From the ease with which wrought iron is cut, we may conclude that an aggregate of ferrite combines with oxygen with greatest avidity, and permits the propagation of a cut with least interruption. As the carbon content is increased, there is a material change in the nature of the metal. In place of the preponderance of ferrite grains, we recognize the formation of cementite, and its union with some of the ferrite to form pearlite—the original mass of pro-eutectoid ferrite rapidly diminishing in prominence. As we should anticipate from the nature of pearlite, no material change is noticed in the performance of these alloys under the cutting torch. Of course, an ultra-precise consumption test would probably indicate a lowering of the efficiency coefficient, but from all appearances, no unusual difficulty is experienced in cutting carbon steels up to about 80 to 90 point carbon. But here, a definite transition is indicated by a distinct laboring of the cutting torch. While the torch will begin a cut with practically the same effort, and proceeds to completion without interruption or unusual delay, yet the kerf is wide and ragged and undeniably distinguished from that of a mild steel cut. It is recognized practice, now, to preheat the piece to be cut, to a black or dull red heat, when the impediment, whatever it was, seems to have been entirely eliminated.

But let metallography explain the sudden change of properties of the steel. As the carbon content of the hyper-eutectic steel was increased, and the proximate mass of pearlite increased, and the pro-eutectoid ferrite correspondingly diminished in volume, until eventually, a point was reached where all of the cementite and ferrite existed in the stratified or laminated relationship of pearlite. This state is

*Paper read before the American Welding Society by Stuart Plumby and F. J. Napolitan.

recognized as existing where the carbon content is between 80 and 90 point—the approximate analysis of pearlite is yet undefined. As the carbon content is further increased, there appears a constituent that we know as pro-eutectoid cementite—in fancy, the cementite which has been ejected from the pearlite growth. It is circumstantial that the presence of this pro-eutectoid cementite is directly responsible for the increasing difficulty of our cutting. But why did preheating of the steel before cutting make such a remarkable difference in the results? To be sure, the rise in temperature might affect the stability of any martensite, troostite, or even sorbite that might have existed, but the temperature was too far removed from the Ac_{321} point to affect the characteristics of the pearlite. And surely the pro-eutectoid cementite was unchanged—and it was this same constituent that we blamed for the difficulty.

Again, as the carbon content is substantially increased, an equivalent interference with cutting is apparent, until, when the carbon content approaches 2.5 per cent., cutting becomes so labored as practically to cease, and no amount of preheating short of incipient fusion will permit it to propagate. As you are aware the metal is now termed "cast iron," and a micro-analysis indicates that in addition to the presence of a certain amount of pearlite and pro-eutectoid cementite, as well as certain foreign and to our discussion, unobtrusive substances, we recognize the presence of the final and most stable state of carbon—graphite. The pearlite constituent exercises a favorable influence upon the operation of cutting—and the pro-eutectoid cementite, while it impedes cutting, is readily compensated by a slight preheating—but the graphite presents an entirely new problem.

We might digress from the subject enough to present some remarks that would prove the fallacy of at least one of the stereotyped explanations of why cast iron cannot be cut—that the melting point of the slag is appreciably higher than the melting point of cast iron. A micro-analysis of the structure of an average cast iron—and by average we refer to a gray cast iron of about three to four per cent. carbon—would indicate a structure identical with that of a hypothetical steel of the same carbon content, except that some of the carbon seems to have been precipitated as graphite. But should that identical pour of cast iron have been cast against a cold iron mold, or otherwise chilled, the carbon would not have been precipitated as graphite and we should have had what we shall call a "chilled cast iron," or a "white cast iron,"—and it would actually have been a hypereutectic steel. Such alloys are not uncommon in commerce, and the fact that operators have been able to cut them with no extraordinary effort, has been responsible for innumerable false claims that cast iron has been cut. Unfortunately, the nomenclature of steels and irons is not clearly defined, and undoubtedly, a chilled cast iron is but an extension of the hyper-eutectic series. The melting point of an iron-carbon alloy is a constant of its composition, whether, in the solid state, the metal exists as a typical cast iron or as a steel. Long before the point of fusion, the carbon and the iron exist in one relationship, that of austenite. The conditions affecting the pouring of a melt of cast iron would determine the final state of its constituents—and we might as readily produce a gray cast iron or a chilled white cast iron—the carbon as graphite or the carbon as in cementite. In either event, the melting points of the resulting products would be identical. We agree that chilled cast iron can be cut with comparative ease, notwithstanding that its melting point is lower than the melting point of the slag produced. It is evident, then, that the melting point of slag is not responsible for the difficulty encountered in cutting cast iron.

We had concluded that while the existence of pro-eutectoid cementite appreciably retarded cutting, the presence of but a comparatively small amount of graphite completely prevented cutting. The phenomenon, if it were true, is unique, for it would pre-suppose the incombustibility of carbon. Science contradicts us immediately. In fact, our own welding practice belies us. We might point to the reaction accompanying the removal of carbon from automotive cylinders by the oxygen method—or, leaving our immediate field, we might mention the explosive combustion of carbon in ordinary gun-powder. We are forced to conclude then, that far from retarding the combustion of the steel matrix, the graphite of cast iron should actually assist it.

We investigated further to determine how much graphite influenced cutting. We obtained specimens of so-called malleable castings of the characteristic "black heart" structure. Such a structure is made in this country by the annealing of white cast iron in which all of the carbon exists in cementite or pearlite, the latter in some cases entirely removed. The treatment decomposes the cementite to precipitate the carbon in minute particles, differing from the graphite of gray cast iron in their extreme subdivision and uniform distribution throughout a ferrite matrix. In making a black heart casting, an oxidizing packing is used in this country, so that while the core is that of a black heart casting, the mass near to the surface is ferrite. We removed this shell of ferrite so that our materials indicated, under the microscope, a uniform aggregate of ferrite and temper carbon. By preheating this piece to a dull red heat, it was cut with the characteristics of a high carbon steel. Then we were satisfied that carbon as such did not prevent cutting, but that the physical state of that carbon was responsible. As plates of graphite, cutting was prevented—but as finely divided particles, cutting was scarcely impeded.

Reconsidering our previous observations in the light of this development, we began to substantiate our first logical hypothesis. We found, to summarize, that ferrite permitted most readily to be cut. Pearlite with pro-eutectoid ferrite did not materially affect the conditions. A completely eutectic composition first suggested a transitory stage. The existence of pro-eutectoid cementite retarded cutting; but preheating of the piece to a red heat readjusted the conditions so that cutting was again as efficient as in the case of ferrite. As the comparatively low temperature produced by preheating was insufficient to effect any change in the physical state of the constituents of the alloy, we were forced to conclude that the addition of heat units affected a definite constant, which we assumed was the heat of combustion of the iron, as the two forces were of like characteristics. Then a constant result from a variable, made axiomatic the existence of a second variable. Our second variable, then, we concluded, was the cooling effect of the stream of cutting oxygen, and a further thought suggested a third variable in the time of chemical reaction between the iron and oxygen. The preheating flames ignited the steel—the cutting oxygen produced combustion—and the propagation of the cut was a natural consequence. But as the carbon content was increased, the speed of the reaction was materially lowered; however, the velocity of cutting oxygen to insure a continuity of oxygen and slag to the bottom of the cut, was a constant. Then, eventually, a point was reached where the rate of combustion between the iron and oxygen was so slow that the heat units liberated from the reaction were dissipated to such an extent as no longer to ignite adjacent masses of metal—and cutting ceased. By preheating the piece before cutting, we add to the forces on the weakening side of the equilibrium, and cutting once more obtained. The heat units so obtained, compensated for the relatively less heat units liberated from the chemical combination of the iron and oxygen in a definite unit of time.

While the pearlite and pro-eutectoid cementite are readily compensated, the graphite carbon effectively prevents cutting by the ordinary means. No addition of heat units short of incipient fusion, by preheating the object, restores the equilibrium. We cannot strengthen further one side of our equilibrium, but we have not attempted to affect the other side. We have made no attempt to reduce the cooling effect of the cutting oxygen. We therefore experimented in this direction, and found that we could so effectively preheat the cutting oxygen that we could restore the equilibrium without preheating the object.

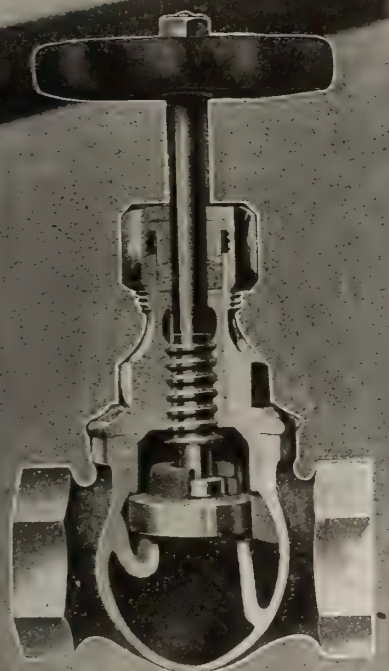
FAIRBANKS-MORSE



An Achievement in Mechanics

EACH individual department of The Canadian Fairbanks-Morse Company, Limited has given industrial Canada a new conception of achievement in mechanics. Each department has established a 100% quality and service standard. This is what enables Fairbanks valves to stand pre-eminent wherever valves are used.

When an engineer specifies Fairbanks valves, he knows that he has selected not only quality of material but workmanship that guarantees perfect operation.

He is satisfied with the reputation and service of the institution that stands behind them. He acknowledges an achievement in mechanics.

Wherever pipe lines are laid—in Canada's great industrial plants—in her immense water systems—in mines and mills—Fairbanks valves are giving a service that is marked by the 100% seal of quality, the standard of The Canadian Fairbanks-Morse Co. Limited.

Our nearest branch will give you the benefit of this service, Our experts will help you in selecting valves and everything mechanical that you require. Make our catalogue your buying guide.

Temperature Control with the Uncertainty Cut Out

The ordinary temperature regulator is an uncertain proposition at best. It operates by compressed air, electricity or water. It often contains complex or perishable parts which get "out of whack" or require replacement. You are never sure that it will operate.

All uncertainty as to temperature regulation is instantly set at rest with the installation of a

SARCO Temperature Regulator

The principle on which this scientific regulator is built insures positive action at all times. It is self-operated—independent of all outside agencies. No levers, gears, diaphragms or complex parts of any kind. Nothing that requires watching or adjustment.

A rise or fall in temperature causes the expansion or contraction of a hydro-carbon oil within a metal spiral. A rod from the spiral operates the valve. Nothing could be more simple—or more certain.

On account of its simplicity the Sarco costs less to make than complicated regulators, a saving that is passed on to you. Sold with the privilege of return after a 30 days' free trial. Write our nearest branch for booklet J-58.

TRADE GOSSIP

Montreal.—Through the inability of the company to procure castings, the Canadian Vickers Co. have been compelled to lay off nearly five hundred men. The shortage is due to labor troubles at Warden King's and the Montreal Locomotive Works, which firms supply the Vickers Co. with their castings.

Dominion Briquette Research. — The Government's lignite briquetting plants established by the Research Council to produce lignite fit for consumption, will be producing by August. It is the opinion of Dr. A. B. Macallum that the new fuel will prove so much cheaper and more efficient than anthracite, that the market for the latter in Western Canada will be closed, and private capital attracted to the lignite fields.

Duluth.—Arguments in favor of the proposed deep waterway from the lakes to the sea were heard at the final hearing of the International Joint Waterways Commission. It was stated that a channel to the sea could be completed in shorter time than the Eastern Atlantic ports could improve their facilities. The commission will hold sessions at Superior, Wis.; Ashland, Wis.; Milwaukee, and finish up at Toledo.

Brockville.—Catching fire at the wharf of the New York Central Railway, at Morristown, the steamer "H. P. Bigelow," owned by the Morristown-Brockville Transportation Co., was totally destroyed. The fire burned the steamer's mooring lines, and she drifted away from the wharf out of reach of the fire department's hose. She burned to the water's edge and then sank. Another vessel will be purchase to carry on the service.

BRANTFORD FIRM SOLD THE BUSINESS

Brantford Emery Wheel Co. Has Been Bought Out by the Waltham Grinding Wheel Co.

Brantford.—Recent transaction places the control of the Brantford Emery Wheel Company, Limited, in the hands of those whose interests are identical with the Waltham Grinding Wheel Company of Waltham, Massachusetts. The Brantford Company has been operating for the past ten years in the manufacturing of grinding wheels and it is felt that the new interests will enlarge immediately production facilities and be a factor of service to the grinding wheel users of Brantford and other parts of Canada.

Colonel Frank A. Howard is to continue as managing director.

The Waltham Grinding Wheel Company is one of the oldest and largest companies of the United States, the originators of the so-called elastic wheel process and have a record of 50 years of service and quality.

The new owners expect to greatly enlarge their production at Brantford.

Use The LONG STEAM for TRAP SATISFACTION

kettles, separators, steam mains. Works against 1 to 200 pounds pressure. Has two outlets and is installed in any position. DOESN'T FREEZE.

The Hamilton Powder Works, Beloeil, P.Q., use them with great success. **Read this letter.**

Dear Sir: We have used one of your steam traps for a long time and have found the same to answer the purpose as well as any seen in operation. We were so pleased with the working of this steam trap last winter that we ordered six more this season and have fitted them up at various points in the works where live steam is used for heating purposes.

(Signed) J. Murray Wilson, Superintendent

Our trap will give you the same satisfaction as recorded above. Investigate and you'll be satisfied, too.

CATALOGUES

The Wellman-Seaver-Morgan Co., of Cleveland, Ohio, have issued a bulletin descriptive of their Wellman mechanical Gas producer. It contains a number of splendid illustrations and a vast amount of information on gas production generally. In the Wellman producer the fuel is fed into the top by mechanical feeders which regulate the rate of fuel, and the arrangement is such that a practically continuous flow of coal is received in the producer, according to rate of gasification. The data given are so complete that the bulletin will be found a useful book for a gas engineer to have at hand for easy reference.

The Bernitz method of furnace lining, which has had very successful applications in a large number of plants both in the U.S. and Canada will be sold, manufactured, and installed in Canada by Messrs. Burlingame & Gardner, who will be located in Toronto. The chief advantage of the Bernitz system is that of decreased cost of maintenance, as the system of introducing air through the furnace lining prevents the adherence of clinker to the wall, thus extending its life far beyond that of the ordinary fire brick. There are also features connected with better combustion, but the Bernitz system bases its claim chiefly on the maintenance feature.

D. K. McLaren's Leather Belting

Good Belting is Not a Matter of Chance

That most important feature of a belt—dependability—is not secured by any haphazard method. Each detail contributing to its manufacture must be as nearly perfect as possible.

Consider these factors of D. K. McLaren's Belting.

The Hide—Selected from the **backs** of the choicest steers. The back is the strongest part.

The Tanning—Genuine British Oak tanning by skilled workmen impart to the leather that mighty toughness and flexibility characteristic of D. K. McLaren's Belting.

The Result—A belting that can be depended upon at all times—a belt with minimum stretch and minimum slippage.

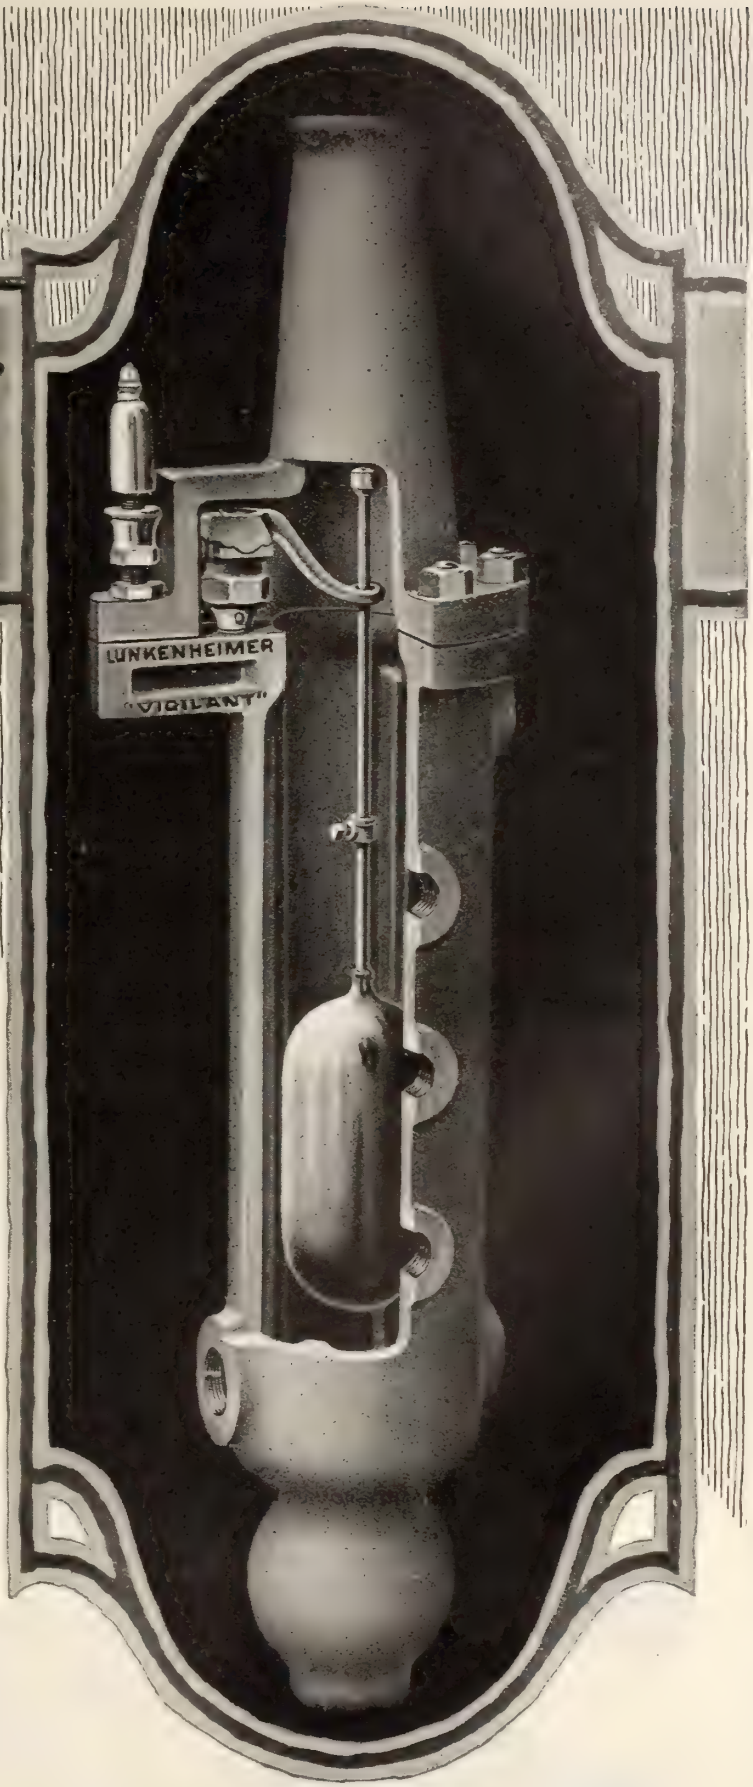
Safety —always



The safety of the steam boiler depends in a large measure on the maintenance of the proper water level, it being apparent that an excessively high or low level will result disastrously. To insure this safety —*always* is the purpose of the

LUNKENHEIMER "VIGILANT" SAFETY WATER COLUMN

which will sound an alarm and notify the attendant should the water approach either danger limit. It thereby protects life and property and by assisting in the maintenance of a uniform water level contributes to economy in the use of fuel.

The "Vigilant" Safety Water Column is a boiler appliance of merit, and is specified when safety and economy are paramount.

Made in a variety of sizes to suit all makes of boilers and from the extensive line of Lunkenheimer Water Gauges and Gauge Cocks a combination can be selected to suit every individual installation.

Specify LUNKENHEIMER and insist on having the genuine. Your local dealer can furnish them; if not, write us.

The complete line of Lunkenheimer Water Columns, Water Gauges and Gauge Cocks is illustrated and listed in Booklet No. 519—DC. Write for a copy.

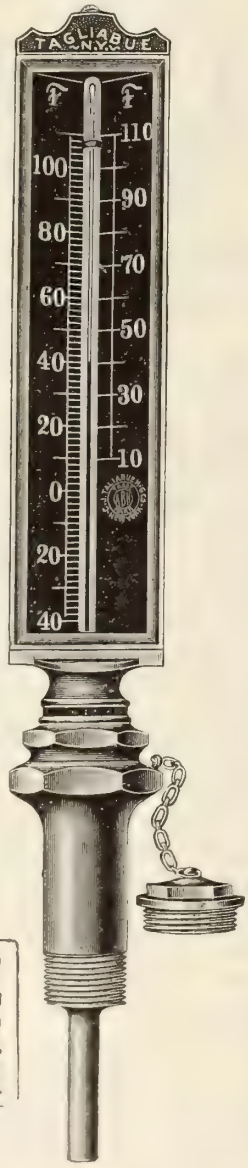
TAG
Self - Operating Pressure Controller

It wouldn't be economy to lose steam through leaking joints, nor is it economy to supply more steam than is needed.

The TAG Self-Operating Pressure Controller prevents the second form of waste.

On any feed pipe, no matter what form of energy or power, the TAG Controller automatically regulates the supply. You can't supply too much and, unless the quantity or pressure fails, you can't supply too little.



The TAG Controller is simple and strong in construction and operates with positive accuracy.

Unlike the hand valve, the Controller allows no more variation than a small fraction of a pound, and you don't have to watch it. It operates itself.

It saves fuel; it saves labor.

These Men are America's Leading Combustion Experts

Every step of the training has their careful censorship, giving you the fruits of their broad and successful experience.

Hays School of Combustion
1108 State-Lake Bldg.
Chicago, Ill.

Better Jobs— Bigger Salaries

Let These Men Show You How to Get Them

Are you interested in sure and rapid advancement to a really worth while position in one of the best paying professions in the country today? If you are it will pay you well to read this announcement. It tells how you, with or without previous training, can prepare yourself in a short time for an attractive position that insures a lucrative salary and an assured future.

Remember—this profession is a new one—unlike all others, it is still uncrowded—and the demand for trained men far exceeds the supply. That's why your services will be in demand when you have acquired the necessary training. That's why you can count every effort a sure and wonderfully profitable investment.

Easy to Learn— No Experience Necessary

In most professions, to become proficient, long periods of intensive study, followed by years of hard training, are necessary. In this new profession—Combustion Engineering—the necessary training can be acquired in a few short months. Why? Because all the knowledge and experience—all the scientific research and experiments—all the labor and study of seven of America's leading Combustion Engineers have been condensed and classified to such a remarkable extent that what formerly required years of study can now be learned in a fraction of that time.

This training from the very first can be applied to the practical every-day problems of any power plant. At some point in the course you must spend some time in power-plant work if you have not already had the experience. That may prove to be your field or you may make it the stepping stone to an executive position. In either case your services will increase in demand and value as you progress in the training.

America's Leading Combustion Engineers Teach You

On this page are photographs of our educational staff. Probably you know some of these men personally. At least, all or most of them, are known to you by reputation.

Jos. W. Hays is the author. His reputation as a writer on Combustion Efficiency is world wide. In this course he has surpassed himself. Every lesson, every chapter, is written in such an interesting, comprehensive way, that the reading of the course is as pleasant as it is profitable.

Associated with Mr. Hays as reviewing and advisory editors are **I. E. Moultrop, W. L. Abbott, Jos. Harrington, Fred R. Low, David Moffat Myers, Prof. S. W. Parr and Arthur L. Rice.** These names alone are proof positive of the thoroughness and completeness of the course.

Especial attention has been given to make this course easily understood by everyone. It is stripped of all unnecessary technicalities and is written in a way that you can quickly grasp and understand. It is prepared especially for the man on the job—the busy man in office or boiler room who can commence putting his knowledge into practice the moment he starts the course.

Send for this FREE BOOK—TODAY

To enable you to get a better idea of just what this course is—just what it covers—why it is a guide to a better job and a bigger salary—why it enables *you* to cash in on the big salary awards that fall to the Combustion Expert—to make all these things clear to you, we have prepared the book "Opportunities for the Combustion Expert." Send for a copy of this book today. It's free.

Mail the Coupon

Simply fill in the coupon and mail it to us. We'll send you a free copy of "Opportunities for the Combustion Expert" by return mail. Time is valuable. Get started today while the opportunities are greatest. Mail the coupon—Now.

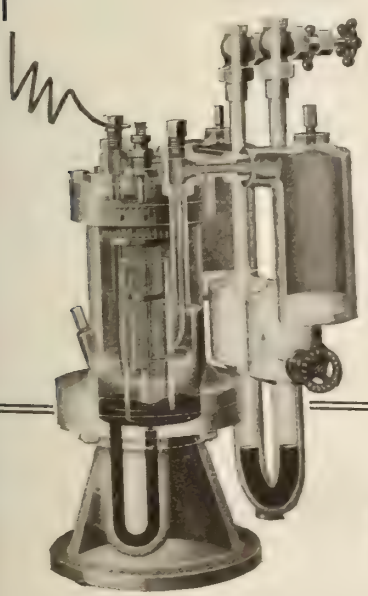
Republic Flow Meters

The Electrically Operated

Electrical Operation Means Accuracy!

Accuracy Means Lower Costs!

You are ready to concede that flow measurement is a great advantage to any steam plant. But do you know of the advantage that the electric method of operation has over any other system.



Dependable records where they can be conveniently read under all conditions! There in a nutshell you have the advantage of the electrical system—that exclusive feature of Republic Flow Meters. It matters not how inaccessible the points of measurement may be, the Republic System assures **convenience** and **accuracy.**

Where there's **accuracy** there's economy—particularly in fuel. Where there are Republic Flow Meters less fuel is consumed, which is an important factor in these days of fuel shortage.

Republic Flow Meters claim your attention. Study the illustrations herewith and then write to us for complete explanation of their application to your plant.

ANNOUNCEMENT!

Burlingame & Gardner, Engineers

announce the opening of offices in the Stair Building, Room 110, 123 Bay Street, Toronto, and will specialize in the

BERNITZ SYSTEM

of

Furnace Wall Construction

It consists of new and scientifically designed furnace wall construction for the purpose of eliminating clinker formation. Clinker formation is disastrous to furnace linings, and restricts the capacity of the furnace. The Bernitz System effectually prevents clinkers from attaining a shelving.

Our new offices in Toronto place us in a convenient position to fully explain the system and its merits. When we install the system a competent staff of engineers superintend the construction and the placing of the boiler in service. The installation is then guaranteed to give the service for which it is recommended.

The installation of the Bernitz System is inexpensive—and that it is effective is attested by its use in numerous large and small boiler plants throughout the country.

A competent engineering staff is ready to co-operate with you at all times on your individual combustion problems.

We have issued an interesting and instructive booklet on furnace efficiency—May we send you one?

BURLINGAME & GARDNER

TORONTO, ONTARIO

Is There an Alien Menace in Canada?

IN THE years of war, people were quick to grasp the possibilities of danger that lie in Alien sympathies. But people quickly forget, and therein lies the danger for it is in the insidious breaking down of the ties of loyalty, that goes on in the piping times of peace, that makes the menace of the days of war.

In "The Stranger in Our Midst" the simple story of a school teacher's experience in foreign settlements in the West there lies a reproach and a warning, a reproach in that such things can be, and a warning that they may not happen again.

This is only one of the many stories and articles that make the June 15th issue of MacLean's Magazine of outstanding interest.

These are some other points of interest:

FICTION

"The Little Warrior"—Pelham Grenville Wodehouse's inimitable story.

"The Parts Men Play"—Arthur Beverly Baxter.

"The Sunset Homesteader"—Will E. Ingersoll.

"The Beetle and the Butterfly"—C. W. Stephens.

ARTICLES

"What Must Be Done?"—Mrs. Murphy's suggestions of a remedy for the drug menace.

"We Must Reform Dress"—Marian Keith.

"Gentlemen of the Fourth Estate"—The story of men who begin life in newspaper offices.

The Best From Everywhere

In the Review of Reviews department will be found the best articles from all magazines and periodicals the world over. Look at these titles and authors:

"Belgium Has Come Back"—by Frederick Palmer.

"How the English Came to Be"—by Rudyard Kipling.

"Eight Billions Wasted"—by Thomas V. Merle.

"Mankind Needs Change of Heart"—by Sir Philip Gibbs.

"Give Labor a Square Deal"—by Charles M. Schwab.

"The Slow Conquest of America"—by Forrest Crissey.

"Know Your Own Car"—by Alexander C. Johnson.

"Sending Pictures by Telegraph"—by Milton W. Stoddard.

Carrying The Peak On Any Kind of Fuel

A difficult Problem was solved at the Spicer Mfg. Corp., South Plainfield, N.J.

Four boilers can easily carry heavy overloads and maintain the steam pressure at 175 lb. gauge regardless whether bituminous, straight anthracite or a mixture is being burned by their six.

DETROIT "V" Type STOKERS

Four of these stokers (at the left) were installed under the 150 horsepower boilers in 1916. Their satisfactory performance in burning the poor quality coals available at that time, resulted in a repeat order for two additional Detroit Stokers (at the right) with Detrick Flat arches for the 300 horsepower boilers that were installed in 1918. The plant was designed by Henry R. Kent & Co., Engineers of New York City.

Detroit "V" type Stokers save coal and labor. They will burn low quality coals smokelessly on natural draft up to 200% boiler rating. Constantly increasing repeat orders are indisputable evidence of satisfactory performance under widely varying operating conditions.

Consultation with our engineers regarding your specific combustion requirements is invited. Catalog "P" gives full details. Write.

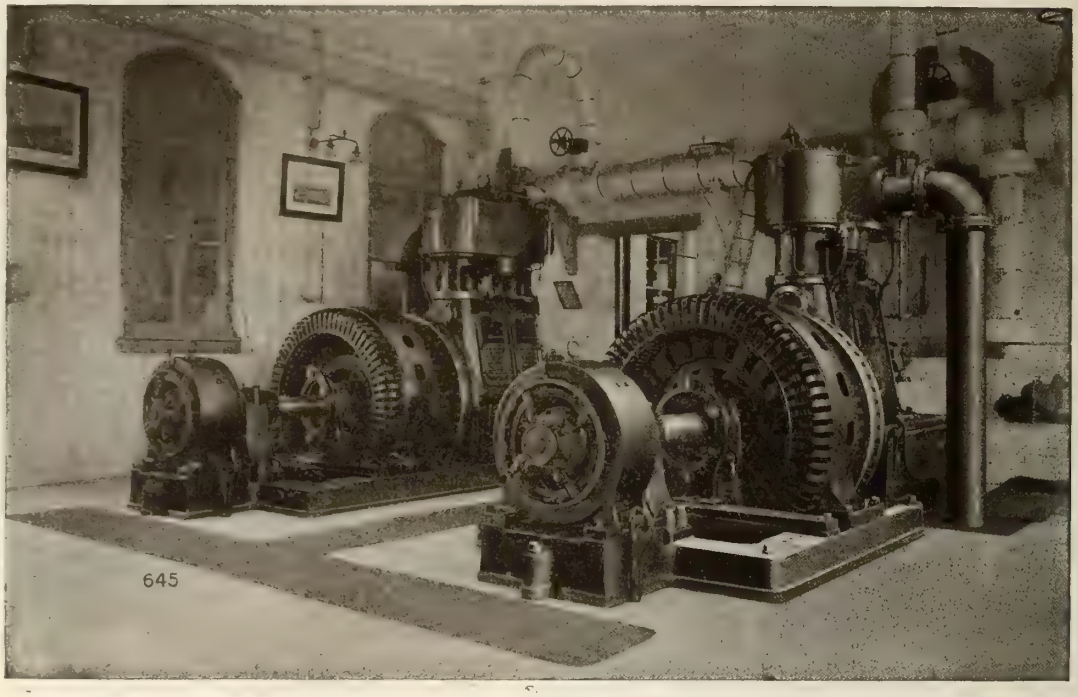
LAURIE & LAMB

Power Plant Equipment



Belliss & Morcom Engines installed in McGill University Power House. Total Horse Power, 1010 B.H.P.

Belliss & Morcom, Ltd., Engines and Air Compressors

To the Engineers at the Convention

Your attention is directed to the high standard of quality represented in the design of Bellis and Morcom Engines and Air Compressors, which is characteristic of all Laurie and Lamb power plant equipment.

Our engineers are experts on power plant economy and efficiency. They are at all times prepared to advise and co-operate in every way to secure the best results in your plant. Put your most difficult problems up to them.

A Partial List of Laurie & Lamb Equipment:

Steam Engines	Condensing Plants	Hydraulic Pumps
Gas Engines	Centrifugal Pumps	Hydraulic Accumulators
Oil Engines	Boiler Feed Pumps	Pressure Filters
Diesel Engines	Water Wheels	Gravity Filters
Steam Turbines	Water Meters	Water Softening Plants
Air Compressors	Hydraulic Presses	Refuse Destructors

Prompt Shipments and Installations

Worthington Hot Water Turbine Meter

Every three minutes a completely assembled Worthington Meter

FOR checking up on boiler performance, a Worthington Hot Water Turbine Meter is absolutely essential. It is companion apparatus to CO_2 recorders, coal weighing scales and similar efficiency promoters.

Worthington meters are standard Worthington equipment, working in close co-operation with Worthington condensing apparatus and power plant equipment to force boiler room efficiency. Each Worthington meter is representative of 80 years of Worthington experiment, improvement and manufacture of pumps and pumping machinery for power plant service.

For any liquid and every measuring condition, Worthington can furnish meter service. And the advice and service of the Worthington engineering department is to be had for the asking.

Other Worthington Products:

Steam, Power, Centrifugal and Water Works Pumps, Meters, Oil Engines, Condensing Machinery, Air Compressors, Vacuum Pumps and Water Wheels.

DEPARTMENT OF LABOUR
Ontario Government

Minister: Hon W. R. Rollo **Deputy Minister: W. A. Riddell, Ph.D.**

NOTICE TO STATIONARY AND HOISTING ENGINEERS AND STEAM PLANT OWNERS

Everyone operating a **Stationary** steam plant of 50 B.H.P. or over, and everyone operating a **Hoisting** steam plant working at a pressure of 20 pounds or over, irrespective of horsepower and used for hoisting in structural operations or excavating purposes, in the Province of Ontario, must hold a certificate from the Board of Stationary and Hoisting Engineers. Application forms will be forwarded upon request.

After January 1, 1920, all stationary steam plants in the Province of Ontario must be registered with the Board of Stationary and Hoisting Engineers. Application forms will be forwarded upon request.

All applications should be mailed to the Chairman of the Board. W. C. McGhie, Department of Labour, 15 Queen's Park, Toronto.

NOTICE TO MANUFACTURERS, DEALERS AND USERS OF STEAM BOILERS

All steam boilers built in, or entering, the Province of Ontario, and boilers exchanged or repaired, are subject to Government Inspection as prescribed in the Steam Boilers' Act, 3 George V., ch. 61.

Before any work of repair or alteration is commenced on any boiler, notice must be sent to the Department stating the nature and extent of the repairs or alterations proposed to be made. If the Chief Inspector should consider such repairs or alterations of an extensive character, the boiler must be inspected in accordance with the Regulations by an Inspector authorized under the Act.

All communications should be addressed to the Steam Boiler Branch, Department of Labour, 15 Queen's Park, Toronto. D. M. Medcalf, Chief Inspector of Steam Boilers.

MONCRIEFF'S

"UNIFIC" GAUGE GLASSES

The British Navy uses "Moncrieff's" "Unific". It is the kind that lasts.
It is a special feature of the "Unific" that it does not readily corrode; resists extreme changes of temperature and withstands the highest working steam pressure. In consequence it has a long life, justifies a higher price than the soda lime glasses, and is, indeed, the more economical purchase in the end.

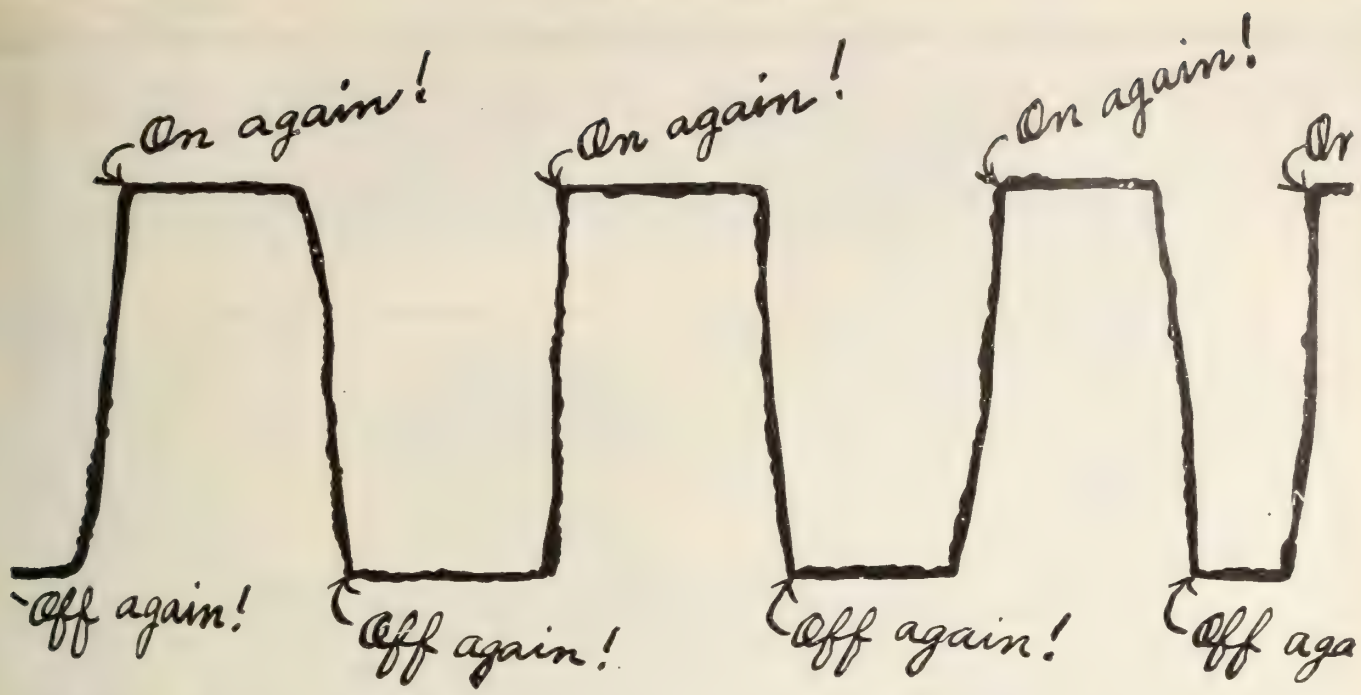
(SOLE MAKER)

9, Westfield Road Birmingham Eng.



Off Again, On Again, Gone Again, Finnigan. That's Hand Regulation in the Average Pulp and Paper Mill.

Above we show exactly what happens when you attempt to control boiler feed by hand. It's simply a case of "off again" and "on again."

Hand regulation cannot give economical results because the operator does not know what is going on inside the boiler. The Copes takes care of every fluctuation automatically. It stores heat when heat should be stored. It gives up heat when heat should be given up.

PAPER AND PULP MILLS

find the Copes to be an excellent investment because the Copes automatically takes care of the large quantities of steam that are used suddenly and periodically. The Copes does it EFFICIENTLY.

Slugs of water in steam frequently spoil the "batch." Copes prevents this spoiling because with the Copes there are no slugs.

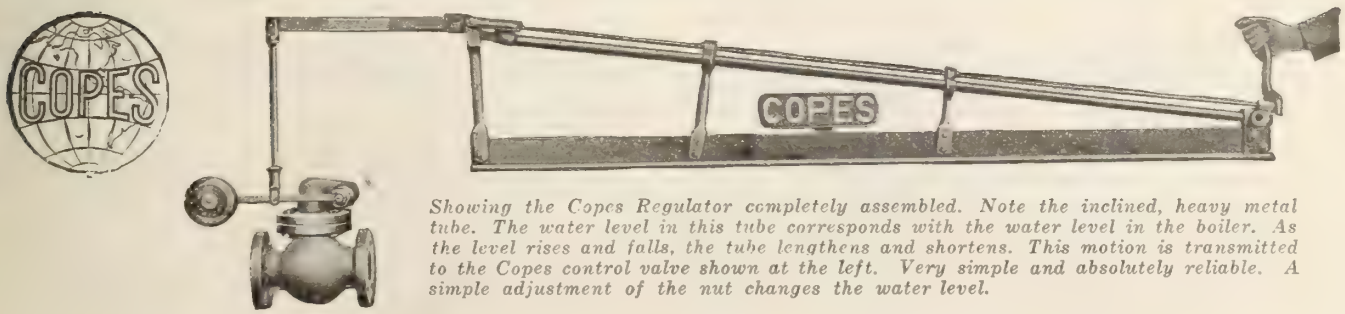
CANADIAN REPRESENTATIVES:—Allen General Supplies, Ltd., Toronto, Ont.; H. N. Brown, P.O. 620, New Glasgow, Nova Scotia; Mason Regulator & Eng. Co., 153 Dagenais St. (St. Henry), Montreal; Engineering Apparatus & Supply Co., 210 Confederation Life Bldg., Winnipeg, Manitoba.

Write Chas. C. Moore & Co., Engrs., 618 Mutual Life Bldg., Seattle, Wash., if you reside in British Columbia.



Showing the Copes Regulator completely assembled. Note the inclined, heavy metal tube. The water level in this tube corresponds with the water level in the boiler. As the level rises and falls, the tube lengthens and shortens. This motion is transmitted to the Copes control valve shown at the left. Very simple and absolutely reliable. A simple adjustment of the nut changes the water level.

POWER HOUSE BUYERS' DIRECTORY
